> ...:-(

Uh-huh. Actually, the address I mentioned was only one way of shortening
the screen, and that way only applies to my own system as far as I know.
The documented way (suggested by someone who didn't know I knew nothing
about assembly) is:

```
dc.w $a000
-42(a0).w
```

Apparently this is how you check the line-a table to see how high the
screen is.

Does anyone know how this could be accomplished through Peeks and Pokes?
I am using Personal Pascal, which has no "asm" call in it so that is
pretty much what I am limited to. I also have Tackle Box ST, if that
helps at all.

From what I have learned from the NET, line-a works but is not gauranteed
to work on future computers. I agree with almost everyone that
shortening the screen is not a nice thing to do to future users of Atari
computers, but that is the best way to get the effect I want. I could
use a window (as was suggested) but that is SLOW. Programs like Stalker
3.x that do use Windows look great, but they can't keep up with my 2400
baud (Supra 2400 Plus, actually) modem. I hate waiting for the text to
catch up with the modem. Anyway, based on the comments about shortening

the screen made by people on the net, here is what I will be doing:

1. The status bar is optional. If you have a system that can use it,
great. If not, just turn it off. For those who don't use it, a keypress
will be enabled that brings up a status report.

Not sure why I numbered that...:) It seemed right at the time.
Now that news is flowing again, perhaps I'll be able to see the responses
people make. I missed most of the thread while things were going crazy.

Thanks for any help. It is appreciated.

I should have mentioned in my first post that my modem is not a standard
2400 baud modem. It is a Supra 2400 Plus. It it uses a compression
protocol when it can, so the text was coming across at around 4500-5000
baud isntead of 2400. This was with a screen accelerator installed. It
didn't fall far behind, of course, but enough so that the wait was
disturbing.

This is true, I suppose. It is more compatible and a great deal easier
to use for the novice. The down side is that it is slower and an agany
to implement...:)

> implementation.

Yes, the safest is through using the VDI. The Line-A calls do work for all Atari computers in production, I'm told, but they may not work on future computers. There is also the problem of working with MiNT. If I shorten the screen and a user starts an editor in the background, unpleasent things would happen. The way around this is to have the status bar as an option (which I elected to do). Then there is the problem of screen modifications like Overscan or the others. This is a fairly sticky problem, but not fatal. If the status bar works on your particular setup, use it. If not, turn it off and press Alt-S when you want to know what is going on (a dialog of information will appear if the user does that).

This is fairly frustrating...:)

>

>
> Hmmmm, you're already in dangerous territory - the address you mention
> is almost certainly not the same across TOS revisions, and could
> conceivably change within a TOS version due to a screen accelerator.

Yes, you are right about that. I should not have mentioned the $2AB2 address, since I knew it was only really valid for my own system or other systems like it (TOS 1.4). A more proper way to do it was mentioned to me, which is to do a "dc.w $a000" and then check "-42(a0).w". This would tell me the height of the screen. I am using Personal Pascal (with Tackle Box ST) though, so assembly language doesn't help me out a lot. I wish it did. Even so, I know next to nothing about assembly anyway.

Thanks for your comments.

Well, you get IBM compatable fonts with Stalker, Trapido, and
Harlekin already, I think another one would be a waste of time.

Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Someone recently put a betatest version of the hermes uucp software
at atari.archive and I have gotten the files and configured them as would be
necessary to access my UUCP information/account. Only problem is that I can
not figure out which program is supposed to set up the environment. I am
done with the config.sys and active, etc. in the other various directories,
and now that I am finished, even login doesn't work so I can make a test
mail message and see how the header reads in the spool directories.

To top it all off, there is no uupoll program to run uucico. Any help out
there? Also, if at all possible, I could stand to hunt down the source
code to the uucico program as I will need to once again add another login
step to it.

>according to all I've read, there is no "legal" answer.

there IS a legal answer (just not the one i want to hear :-) and that is
to use GEM (VDI and/or AES). another alternative would appear to be to use
MiNT/MGR. i am now leaning to the latter (tho i still have to look into
pinging individual pixels under MGR) for my own use...

the problem with Physbase and the other "schemes" i was asking about is they
really break under a multitasking environment (like MiNT or its descendent
MultiTOS). this is because this info is global, not local to a "window" or
"task". i understand this. and hindsight is wonderful.

1526. Anyone interested in hooking an Atari 3.5 to a PC?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-15 05:52:54 UTC
From: plate@cdsmn.mn.org
Message-ID: <1992Apr15.055254.14862@cdsmn.mn.org>
Source record: 44774

I recently took some time to interface an SF314 external 3.5 floppy to my PC at work so i could use it to transfer files. It wasn't as plug and play as I thought it would be.

Is anyone interested in a "How To" on this topic? Before I spend a lot of time on it, i want to be sure there is some interest. I have seen articles about attaching an IBM type disk to the ST, but not the other way around.

The modification is cheap, easy and you can still use the SF314 on the ST.

No soldering, etc.

I will post if I get a response.

Regards,
Doug

Friedrich>to older TOS? Is this an additional installation.
Friedrich>
Friedrich>Any comments would be greatly appreciated.
Yesterday I installed the TOS Expansion Board from Hard & Soft in Germany.
If you have your CPU already socketed you can put this card under the CPU.
There a three soldering points, two to the old CE-Pin of the old ROM's
(you have to draw them out of the socket) and one on the CE-pin of
one of ROM sockets. You can switch without any problems between the two
ROM-Versions. If you don't have you CPU socketed you may solder the board
on top of your CPU or use the so called speed bridge for connecting the
board via the mega bus.

I' ve seen ads of artifex the german distributor of the TEC. They also have
new versions of the TEC for soldering on top of a CPU or for the mega bus.

Hope that helps

OK, thanks to a number of folks, I have been able to disable the
upper 2 megs of Ram on my 4 meg upgraded Mega 2 ST. And it has narrowed
down my problem...
Once I disable this 2 meg bank of ram (which is on a Xtra Ram board),
I get NONE of the hard drive write errors and subsequent sense 04 messages
that I get when copied the same K of files WITH the ram activated.
These errors only occur with programs that load as much as possibly from
source before writing, such as cheetah, neodesk, vault, etc... never get
the errors straight from the regular desktop, since it does a file at a time.
I have thoroughly checked the memeory chips with different ram testers, and
they appear fine, never got an error...

Thus, what I am left with is the following, normal programs, ramdisks,
etc are able to use this extra 2 megs of ram just fine, but not the Hard
disk when attempting large writes. Any idea's? DMA chip possibly? How does
it interface with the ram banks?

Getting closer to solving this bugger of a problem... :)

From: meulenbr@ce.philips.nl
Message-ID: <1992Apr15.100541.25159@philce.ce.philips.nl>
Source record: 44778

Hi,

I have a TT with a HD floppy drive and an ajax chip.
I'm trying to access the drive using my own software, and I'm accessing
the chip directly. I can access normal 720 kb floppies, but I cannot
access 1.44 M floppies.
I did already double the steprate for HD floppies.
Should I one way or another program the ajax so that it is in HD mode,
or does it auto sense.
The first request that I make fails with sector not found.

Thanks for your help!

Well there IS such a driver mechanism. It's called VDI. That's what VDI drivers are fore, and that's why one should to all screen output with VDI functions.

Yes, This is exactly what I did with my ST. Worked like a charm. The only thing
that you need to watch for is reversing the cable when you plug it into the
new drive. You can tell its reversed because the drive lights go on as soon as
you turn the computer on and they stay on constantly.

1533. Trapping the RESET Vector

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-15 16:20:04 UTC
From: cordes@ac.dal.ca
Message-ID: <1992Apr15.132004.5082@ac.dal.ca>
Source record: 44780

I've been struggling with a bit of code for some time now and I'm finally going to give in and ask for some help.

How does one go about trapping the reset vector such that your program may re-enter a specific point when the system rebooted from either the reset switch or via CNTRL-ALT-DEL?

I've passed the magic number $31415926 to resvalid ($426) and put the address of the routine I wish to enter into resvector ($42A). What more do I need to do here? There is a brief note at one point in the Hitchhiker's Guide which says the stack pointers now contain garbage, but I'm not sure how to save them reliably, if in fact this is my problem.

As things now stand, when I press the reset button, my monitor goes black and then the system freezes. Sometimes I get that slight high pitched squeal that the machine makes if you hold the reset button in too long. I'm forced to do a power off to reboot.

Any/all help would be appreciated.

so what are "native graphics modes"? is this, too, something that will
go away in the future?

>Wrong. Novell/DR stil makes X/GEM (on top of FlexOS) and believe it or
>not, they care about existing Atari programs (if you don't believe me:
>contact Digital Research Monterey).

is X/GEM gaining exceptance anywhere? i remember reading about this a year
or so ago and have not heard anything since. does atari plan to use this
when they get their unix thing geared up?

>>no, but you could mix GEMDOS/BIOS with XBIOS, if you know the screen
>>address.
>
>How?

for an example, look at mgif. i use printf (GEMDOS which probably calls
BIOS, i don't remember) and twiddle pixels after finding screen with Xbios.
it works fine on a "normal" ST, any TOS, with 640x400 screen. it no longer
uses Line A, but does use Physbase. it won't run in the background under
multitasking but then i don't really think that is necessary for an
interactive image processing application. i know there are acceptions
but you get what you pay for...

ok. julian (and others) have convinced me that for portability of graphics
applications (including changing fonts for textural applications) that the
only acceptable way is GEM (VDI and/or AES). this means that for my own
use, i will continue to hack with formerly "legal" techniques, but for things
i choose to share on the net, i will at least try to be more "config friendly".

this means i have to pump myself up into the belief that it is actually fun
to program GEM applications. this is not what i recall, however. the other
alternative is to offer what i have (including source) and let someone else
worry about portability. the way i look at it is i am going to go thru an
exercise where 60-80% of the code is UI, then i might as well find a publisher
and sell the thing. now i'll have to dig back into my gem toolbox...

thanx...

I don't think there is a TOS 1.3. If you have less than TOS 1.4, you should get a copy of FATSPEED and stick it in your AUTO folder. I think this will solve your problem.

My HD writes very fast, and I am using TOS 1.2 with FATSPEED.

Also, be sure to get a copy of foldrxxx.prg (unless you are using an ICD host adaptor, in which case the ICD software takes care of extra folder allocation). I think that with ANY version of TOS there are at least a couple of little AUTO folder "bug fix" type programs one needs. They are different for the different versions of TOS.

TOS 1.3 Doesn't exist. You may, as me, have TOS 1.2 which is supposed to be quite a bit slower than 1.4, handling the harddisk. I notice the same delay as you do when searching or creating a file, the raw read and write actions are however very fast. Perhaps you could try an upgrade to 1.4? I use a notoriously slow atari megafile 60.

Perhaps. Think of it. Why should Atari support something like ST-Medium on future machines (if it costs money)?

>is X/GEM gaining exceptance anywhere? i remember reading about this a year
>or so ago and have not heard anything since. does atari plan to use this
>when they get their unix thing geared up?

X/GEM has (yet) nothing to do with X or Unix. It's a GEM version for FlexOS, DR's realtime multitasking OS for Intel machines.

>this means i have to pump myself up into the belief that it is actually fun
>to program GEM applications. this is not what i recall, however. the other

Perhaps you should try it a second time. VDI and AES really aren't that different than other operating systems (especially the simple line drawing stuff and so on).

1538. TOS upgrade

Newsgroup: comp.sys.atari.st.tech

I just opened up my ST yesterday (one week after I bought it) and
I saw that I have TOS 1.4. I've been seeing some postings on upgrading,
my (stupid) question is why?
Also I'd like to upgrade my memory, is there a upgrade kit available
and what should I expect to pay for it? Also are there instructions on
how-to-do-it yourself posted around in case I don't want to spend to much
money.
Thanks,
Jonathan

>order to determine the media change because I've seen that function call that
>returns the "a media change has occurred", "a media change has probably
> occurred", "a media change has definitly not occurred". Weird!
Well, actually it doesn't count anything. Checking the write protect line is
ONLY used to change from "a media change has definitly not occurred" to
"a media change has probably occurred" state. Atari verifies if it has
actually occured by reading the bootsector and checking the serial number
when an access in attempted in "a media change has probably occurred" state.
If serial numbers match the system returns to "a media change has definitly
not occurred" state. If they don't then the system changes to "a media change
has occurred" state.

This is why switching IBM formatted floppies and writing can corrupt the
directory and FAT of the 2nd floppy placed in the drive.

From what I have seen in VDI, it could even be configured to drive vector graphics cards (which would have no frame buffer). These devices uses command/vector lists and X-Y monitors instead of bitmapped RAM and video monitors. Even if they mapped their command/vector list RAM into the computer's main memory there would be no easy way to test or write to individual "pixels" on such systems if you bypassed their driver software.

I have worked with vector graphics systems (used in Avionics) for over 14 years (gad! has it really been THAT long?) and know them quite well.

1541. 'gem' prefix for tcsh?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-17 04:44:39 UTC
From: timg@ncsa.uiuc.edu
Message-ID: <70459@ut-emx.uucp>
Source record: 44788

Hi,

Can anyone tell me if a program exists for generic shells which imitates the 'gem' prefix of gulam?Gem programs started from bash and tcsh are generally mouseless (useless), and often do not properly fill the desktop. If no such program exists, does anyone have any suggestions for writing one?

I presume that such a program would save the screen, do the proper things with the background and the mouse (what gem functions), exec the desired program, and restore the screen in the end. Could such a thing be made to work with MW2 running under mint? I have heard that more than one gem program at a time is problematic.

Thanks,

I plan to get Spectre GCR VERY soon & most likely an SST as well (I have to do some Mac work)..
My question is this: Can I hook a CD-ROM up to my ST that will AT LEAST work with the mac? It doesn't necessarily have to do anything useful with an ST, as long as it acts like a normal mac cd-rom..
Would I need a megatalk board for this or will my ICD adapter be good enough?
Also, I've heard that the Mac 1.44 meg disks are identical to IBM 1.44's..
Is this true? Could I, in theory, take a 1.44 meg Mac disk to my PC, read the 1.44 disk onto hard drive, re-write to an 800k and move to my ST? That would be nice as well.. (I assume that copying files from the ST to a Spectre partition IS possible?)..

>> fashion?

The pointer is returned from Pexec(LOAD_NOGO).
I have fiddled around with this stuff to realize a program load & cache
system as I like it in OS-9/68k.
There are many problems:
You can't manage memory in a clean way (I think).
I install a resident driver that catches Pexec() calls and looks into
its tables if the started program is already cached. If so, I just insert
a buffered data segment, clear bss and go.
Programs are loaded via a micro-loader that starts up, loads the module
and quits by Ptermres().
If you want to do such things:
Care for the actual environment and care for path descriptors, which are
nasty - I got them to work, but I rely heavily on undocumented TOS internals.
Don't wonder if Tempus doesn't work any more - it's not your fault, it's Tempus's,
which fiddles with undocumented fields in his and its parent basepage.

Disclaimer:
I just played around with these.
I don't support it in anyway.
I never did it (next revolution comes for sure :-)

I didn't want to make it available because it is dirty trickery, not finished
and can eventually lead to disk crashes (never happenend), but I hate postings
like 'yeah i got it bunny but i'll bury it in my desk forever and myself'.
If you want the source (Turbo C & 68k) mail me, but don't expect any help from
me. Also don't expect that I remove any bugs. I just dropped it.
Perhaps I might put hands on it again together with somebody but:
another hint: It doesn't lead to anything while you're on hard disks.
Speed increase is insignificant. It wins only on floppies because it doesn't
take up as much space as a ramdisk.

Greetings, Bjoern

1552. disks formatted with DOS 5 and media change

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-19 16:02:07 UTC
From: as327@cleveland.Freenet.Edu
Message-ID: <1992Apr19.160207.23675@usenet.ins.cwru.edu>
Source record: 44849

Hi,

I am working on a file copy program which offers the user the option of continuing the copy (i.e. changing the target disk) if the target is full. The disk change causes no problems if the target disk is formatted on an ST. If it is formatted with DOS 5, all sorts of havoc ensues (including corruption of the disk!).

I know something about the mechanism the ST uses to detect a disk change. I think first, a media change has to occur. Second, the serial number of the new disk has to be different from that of the original. I am puzzled, because I'm reasonably sure a media change is occurring and I think the DOS 5 formatting program puts a serial number on its disks. Am I making a wrong assumption anywhere?

I also have a question about how to force a media change. I don't have any kind of 'official' TOS documentation, so I am just guessing that what I need to do to force a media change on drive A is call 'Mediach(1)' followed by 'Getbpb(0)'. The 'Getbpb(0)' will recognize the new disk and reset the 'Mediach' flag to 0. Any wrong assumptions there?

Oh, yes, and the program I am working on is a new version of 'mcp - Monk copy' with support for copying files larger than the target disk. Any help I get here will go into the new version, which will be called 'docp - directory-oriented copy' and will be distributed under the GNU copyleft.

Thanks!

>and reset the 'Mediach' flag to 0. Any wrong assumptions there?

Just one wrong assumption: you do NOT want to do the Getbpb(0) call
yourself, because that will clear the media change status (as you
surmised), and GEMDOS will thus never see it. It is GEMDOS that needs
to be aware of the media change. So, what you need to do is follow
the Mediach(1) call with a call that causes DOS to access the disk.
A good way to do that is Fsfirst("a:\\x, 0"); -- it doesn't matter w
whether there is or isn't a file named 'x' on the disk, when DOS tries
to read the disk, it will get the 'media has changed' error status
back from the read (because you forced that status with your Mediach()
call), and then DOS will do the Getbpb() to clear the status. DOS
also punts all buffered information about the disk when it sees the
media-has-changed status, and begins rebuilding internal buffers after
it learns about the new disk format and layout using Getbpb().

On a floppy disk, media change is easy to force, it's always just a
Mediach() followed by an Fsfirst(). On a hard disk (which may have a
driver which doesn't understand forced media changes) you may need to
install a little temporary driver intercept to handle the mediach.
I have code (Madmac assembler) to do that if you need it. Generally
you only need to force media change on hard disk if you've directly
changed the FATs or directories using BIOS calls.

```
In <1992Apr15.132004.5082@ac.dal.ca>, cordes@ac.dal.ca writes:
: How does one go about trapping the reset vector such that your program may
: re-enter a specific point when the system rebooted from either the reset
: switch or via CNTRL-ALT-DEL?
:
: I've passed the magic number $31415926 to resvalid ($426) and put the
: address of the routine I wish to enter into resvector ($42A). What more do
: I need to do here? There is a brief note at one point in the Hitchhiker's
: Guide which says the stack pointers now contain garbage, but I'm not sure
: how to save them reliably, if in fact this is my problem.

Among other things, the intelligent keyboard got a reset and the 200 Hz system
timer has to be restarted. I have used the following code fragments to implement
a SIGRESET in my version of the GNU-C library (which was used eg. to build
emacs). It still has some problems. You can save some files (i have used this
in a very old version of bash to save the history), do screen i/o and even come
back to the shell (i've tried it with Master), but sometimes the machine hangs.
Maybe someone else can fill in the holes.
I have once seen a version of some basic compiler echoing "Reset" and returning
to the shell when the reset button was pressed, but this was with the old
("mushroom") TOS 1.0 booted from disk. The MAC-emulator Aladin could also
reboot itself after a RESET - but this too could be a different story.

: Any/all help would be appreciated.

Hope this helps you

- Edgar

You might want to try checking some of the games machines like
SEGA or something similar. I remember seeing this type of
device at TOYS 'R US as well as in Consumer's Distributing.

1557. HERE it IS. The fix for Think C V4.0 Source Debugger

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-20 03:17:20 UTC
From: carter@cae.wisc.edu
Message-ID: <1992Apr19.221720.14639@doug.cae.wisc.edu>
Source record: 44854

Ok, ok ok ok. I know for the longest time you have waited, but I had
exams to fail, women to love, and bills to pay...

Pay attention to the procedure....CAREFULLY.

If it doesn't work for you, I won't be held responsible.

Open the THINK C source debugger and look for the CODE resource segment
using ResEDIT.

After you find it, open code resource #2.

Search for the HEX sequence:

6112 00d4 0000 0000 610a 00d8 0000

Replace with:

6112 00d4 0000 0000 610a 0000 0000

Close and save your copy!

Also, since this negates access to the FPU, DON'T use this version to debug
any FP software...YOU'LL be SORRY!!!!

Ok...now don't say I don't ever do anything useful for this group.

My Theatrics are well worth to listen too...they are even entertaining....

So, NOW....you can use an awesome debugger on the MAC side too...

Although...I am biased towards Borlands Turbo C....

Ok, well enjoy.

Greggy

In article 703612181@neumann.une.oz.au, mmartin@neumann.une.oz.au (Mark Martin) writes:
>
> I am looking for information on the translating source code
>written in C for the Atari ST series to enable it to be used on a Mac.

For heavens sake, Mark, tell the honchos pushing this project that if they want _that_ particular piece of software, then buy the Atari machines! The Atari ST and early Macs such as the MacPlus may share the same 68000 processor but that is about where the similarity ends. Bottom line is that it most certainly is NOT an easy translation to go from the ST to the Mac or vice versa. Just ask Dave Small @ Gadgets by Small and he`ll tell you _all_ about it!

> Any extra speed offered by a Mac is not an important
>consideration as I am told that the programs run quite adequately
>on the current hardware (a Mega4 ST).

What makes them think a Macintosh would make the same software faster? Fact is, an Atari ST is inherently faster than a similar Mac, such as the Mac Plus. Of course, if you pump the software into a MacII whatever with 68030, then you can and should expect a speed increase.

How about emulation? Suggest they buy a few Ataris so they can run this particular piece of software they want but also buy them with Spectre GCR Mac emulators so they can "have their cake and eat it too", so to speak.

1561. HELP!! Programming help needed...

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-20 19:37:03 UTC
From: oracle@iastate.edu
Message-ID: <oracle.703798623@vincent1.iastate.edu>
Source record: 44858

I have a programming problem that I don't have the experience to do myself that I hope someone else may be able to give me a tip on..

I would like to write a program that runs in the background (perhaps as an accessory) that CONSTANTLY monitors the carrier signal on the RS232 port. If the program sees that the carrier dropped, even for an instant, it should lower the DTR signal. The program should stay resident and repeat the task every time it sees the carrier drop. The program should not worry about raising the DTR again.

I have Personal Pascal, gcc, and turboasm, but I don't know how to program something for the background...

Any help writing this (if it's possible, I don't know) would be appreciated.

1562. G++ include files and libraries (for 2.1) [probably clueless]

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-21 00:53:14 UTC
From: dmb@wam.umd.edu
Message-ID: <1992Apr21.005314.6221@wam.umd.edu>
Source record: 44859

The recent GCC 2.1 Zoo on atari.archive contains a new gcc-cc1+, but the corresponding include file Zoo doesn't have any of the G++ include files. When I tried compiling hello.cc with the new 1 meg (!) G++, I got lots of complaints about the obsolete once pragma and then a grumpy "exit code 1" from Gulam.

Is there any way to upgrade to this new version of G++ without having to apply all the updates in the updates directory (and thereby build the library from scratch)? Will this new one even compile hello.cc on my pitiful 2.5 meg ST? One has to worry about any binary that's twice as large as Nethack...

Will the complete distribution in the gnustuff/g++ directory be updated to version 2.1?

Anyone? Anyone? :-)

you need to find out about lint (or gcc -Wall -fstrict-prototypes)
in a hurry. you dont need to carry anything around in your head :-)
about toupper: in most modern C libraries its a function for the very
reason you cite. Also Ansi C prohibhits any of the isXXX() <ctype.h>
macros from eval'ing their args twice. Also, look at the gnuC manual
on how to write safe macros (albeit not portably).

1566. GnuC 2.X <osbind.h> explaination and example

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-21 03:15:48 UTC
From: bammi@acae127.cadence.com
Message-ID: <BAMMI.92May3105948@acae127.cadence.com>
Source record: 44863

Many people (3 mails this morning) have asked me to explain what i
meant by the following article that i posted. An explanation and an
example are attached below:

> as michael suggested its a good idea to move up to current
>patchlevels, especially for gcc 2.X. if you are using mntlib with gcc
>2.1, until they are patched, BEWARE that stuff from osbind/mintbind
>will not produce correct code because of the assumptions made in the
>inline asm()'s about the compiler.

in the osbind/mintbind asm()'s (and asm() in doprint() and a few
other places) we had made assumptions about the compiler that are no longer
true with gcc 2.X. The problem only shows up when -O -fomit-frame-pointer,
and then too it is context sensitive. what was happening was that we had an
optimization there for asm's that needed more than 4 args. we gave them the
looser "g" constraint and made them __volatile__. what this did was it
forced the compiler to eval the arg before pushing it. now if a arg was
computed into a temp (if the args was not in a reggie already, which is the
case most of the time), the temp was created relative to A6 (frame pointer)
(so -fomit-frame-pointer did'nt get a chance to omit either), then later
when we pushed these args, even though we change sp from under the compiler,
A6 was unaffected and the right value got pushed. Now in 2.X, -fomit-FP
actually is much more aggressive. It actually creates temps on the stack,
relative to SP (not A6) and gives the omit opportunity. Now our assumption
fails because we change SP from under the compiler, and when it goes to get
values from temp relative to SP, of course it gets garbage.

here is the Changelog entry from PL77: (see below for an example)
osbind.h:: ++jrb
-- another re-hack needed for gcc-2.0: the optimization that we
used earlier for traps with more than 4 args, making them volatile
and using "g" constraints no longer works, because gcc has become
so smart! we now remove the volatile, and give "r" constraints
(just like traps with <= 4 args). that way the args are evaled
before we change the stack under gcc, and at appropriate times
put into reggies and pushed (or as in most cases, they are evaled
straight into reggies and pushed -- and in even more common cases
they are already in reggies, and they are just pushed). not doing
this with -fomit-frame-pointer was causing the temps (from evaluing
the args) to be created on the stack, but when we changed sp
from under gccs feet, the offsets to the temps ended up being wrong.

Of course you want an example to illustrate what i am talking about:

#include <osbind.h>

```
int mode;
char *prog, *tail, **env;
main()
{
Pexec(mode, prog, tail, env);
}
```

```
gcc -O -S -fomit-frame-pointer p.c
```

Output of gcc 2.X with PRE-patchlevel 77 <osbind.h>

```
#NO_APP
gcc2_compiled.:
.text
.even
.globl _main
_main:
addw #-20,sp
movel a2,sp@-
movel d2,sp@-
lea _mode+2,a0

movl sp@(10),sp@-; notice how we are changing sp without
movl sp@(14),sp@-; telling gcc about it. guess what!!
movl sp@(18),sp@-; sp@(14) etc aint what it they used to be!
movw sp@(22),sp@-;
movw #75,sp@-
trap #1;
addw #16,sp
#NO_APP
movel sp@+,d2
movel sp@+,a2
addw #20,sp
rts
.comm _mode,4
.comm _prog,4
.comm _tail,4
.comm _env,4
```

Output of gcc 2.X with POST-patchlevel 77 <osbind.h>.

```
#NO_APP
gcc2_compiled.:
.text
.even
.globl _main
_main:
moveml #0x3e20,sp@-
movew _mode+2,d4
```

```
movel _prog,d5
movel _tail,d6
movel _env,d3
#APP
movl d3,sp@-;
movl d6,sp@-;
movl d5,sp@-;
movw d4,sp@-;
movw #75,sp@-
trap #1;
addw #16,sp
#NO_APP
moveml sp@+,#0x47c
rts
.comm _mode,4
.comm _prog,4
.comm _tail,4
.comm _env,4
```

Those of you who use mintlib/gcc2.X combination should be aware of this. Hint: it is not hard to apply the tos library updates to mintlib directly, most of the patches just fall in, but of course you have to be careful since all the code is not one-to-one. it is not a no-brainer. ofcourse, you can be lazy and wait for eric to do all the work :-)

Jeff W. says it was supposed to be up this weekend, but no luck yet.

>Is there any way to upgrade to this new version of G++ without having
>to apply all the updates in the updates directory.

Is that what they are. I ignored them.

>Will this new one even compile hello.cc on
>my pitiful 2.5 meg ST?

This is the reason I haven't worried too much. I'm pretty sure 2.5 Meg
(same as mine) is insufficient... unless perhaps you run G++ from the
desktop ;-). I only use a little shell (Mupfel), even though I'd rather
be using MiNT + Bash...

Time to move UP. Trouble is, I really should wait for these new
machines (if only because it will mean cheaper TT / STe prices).

Warwick.

1568. My Golden Image Optical mouse...broken?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-21 03:46:20 UTC
From: genius@sys6626.bison.mb.ca
Message-ID: <XJgkJB2w164w@sys6626.bison.mb.ca>
Source record: 44865

I bought a Golden Image Fully-optical mouse about a year ago. Yesterday, I unplugged my mouse from my TT at home and took it to a friends and plugged it into his ST. Immediately I noticed that the mouse was acting weird, so I just unplugged it and used my friends mouse without further problems. When I got home and plugged my mouse back into my TT (the same thing happens on my ST, so it's not the TT's fault), it was still screwy. What happens is the movement works fine, but when I press the left mouse button, the mouse will 'jump' a few pixels away in the last direction the mouse was moved. For example, if I had just moved up, stopped and pressed the left mouse button once quickly, the mouse would 'jump' about 20 pixels or so up, and then the computer would register the click. If I press and hold the left mouse button, the cursor will act like I was doing just that, but then the mouse won't register any further movement commands and will remain frozen on the spot with the button pressed until I release the button, when the cursor will do its little jump.

My question is...anyone know if this is fixable and how to go about doing the repairs? I'm pretty handy with repairs as long as I know what to do. Or should I kiss my mouse good-bye and buy another one ($60-90). Any hel
p would be greatly appreciated! Please Email or post here. Thanks.

1571. GEM question (raster copy)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-21 15:42:01 UTC
From: rosenkra@convex.com
Message-ID: <1992Apr21.154201.28954@convex.com>
Source record: 44868

having been beaten up about using things like Physbase, i have decided to relearn GEM and write a "proper" portable application. :-)

now i have a question...

i want to use the VDI vro_cpyfm() function to "blit" a raster into a window work area. this requires filling in the appropriate MFDBs (memory form definition blocks). this also requires knowing some addresses. the source address is easy. it is just the raster i want to copy. however, the only way i know how to find the destination address is with Physbase. the program works correctly on a 640x400 monitor. how can i get this address in a more "portable" way so that it will work with ???x??? tubes? all the examples i have looked up so far in books (old) use Physbase/Logbase for this sort of thing so i have no "correct/modern" references in my library.

note that this is now 99% VDI/AES only (no [X]BIOS, except the Physbase call). i want to make it 100%. how? is there a "prefered" method of blitting rasters to a window with arbitrary graphics devices? do you even need to know this address (that rings a bell, but it has been so long ago that i forget if you even need this)? would Logbase be better?

this is for a future GEM-only version of mgif (monochrome GIF/JPEG viewer). so far i am able to open a window, blit the image to wdw work area, and in an evnt_multi loop (timer=0), repeatedly blit the 3 different screens for the "flicker" mode grayscale simulation when the timer expires. this is much slower than the original mgif and the effect is not nearly as nice as before. however, it should run on anything out there (once the Physbase is removed). there are some optimizations i can make, however, tho i don't think the effect will be quite as good as before because of the overhead of evnt_multi/hide_mouse/vro_cpyfm/show_mouse. it also might not be bad on faster-than-8Mhz systems. perhaps the solution is to ask people to increase their clock speeds :-).

thanx...

Upgrade to Sozobon 1.33i. There are several startup modules in the
package, including support for desk accessories, and there is
example source code.

If you have FTP capability, get atari/languages/sozo133i.zoo from
atari.archive.umich.edu.

If you have only email capability, send a message to
atari@atari.archive.umich.edu containing the following line:

send languages/sozo133i.zoo

>be using MiNT + Bash...

The scary thing is that these GNU binaries keep getting fatter and fatter. Soon you won't be able to compile hello.cc on a maxed-out (4 meg) ST! I just had a hell of a time getting Nethack pl10 to compile on my 2.5 meg ST with GCC 1.40 -- I had to disable EVERYTHING, even FOLDXXX, to have enough memory. (Switching to the 20K Sozobon make.ttp instead of the 120K gnumake was also essential.)

I'm afraid to start using G++ for a sizeable project because what will I do when it won't compile in 4 megs any more? (Buy a TT? Not for 1/3 the price of a car.) Is this a realistic concern? Are people out there compiling hefty C++ code with G++ on their ST's? I'd hate to think that such a powerful tool has been relegated to "toy" status due to memory limitations.

From: UweKloss@lionbbs.bs.open.de
Message-ID: <H.RmbDe9oI2j6@lionbbs.bs.open.de>
Source record: 44872

Hi out there!

I am looking for a backup program which doesn't mind
working on a TT and using HD floppies.

Something else, greatly appreciated, would be hints
how I can convince TURTLE that it CAN work on my
system.
I recently got Version 3.00 and tried it, but it keeps
argueing that it can't work with my memory configuration.
The three memory areas it shows for the program,
the ramdisk and the screen DON'T overlap.
So I don't see any problem here.

1576. Sozobon MiNT library version 19

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-21 17:47:16 UTC
From: bigham@hercules.acpub.duke.edu
Message-ID: <2527@news.duke.edu>
Source record: 44873
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

As promised, I have placed a compiled version of the MiNT library for Sozobon C at atari.archive; it should be migrating to atari/mint shortly. It consists of a replacement dlibs.a and dstart.o, a termcap library, and a replacement set of floating point printf/scanf routines. I've also included some (very small) source changes and some advice for those who are interested in building this puppy themselves.

If you have problems, send them to me, and I'll forward them if necessary (I don't _think_ i made enough changes to introduce any bugs, but you never know...). My plans for the near future involve adding lmalloc() routines and rearranging the library so it doesn't drag in so much junk by default, so watch this space for new releases.

```
> Bill Rosenkranz asks a question that basically comes down to:
> How do I find the screen address to put in the fd_addr field of
> the MFDB for doing a blit?

There's a 'trick' in VDI (documented, legal) that lets you supply a
NULL pointer in the MFDB that describes the screen. When VDI sees the
NULL pointer in fd_addr, it knows the MFDB is for the physical screen,
and it ignores all the other MFDB fields and uses its internal info on
how and where the screen is physicall configured.

The following source code is a module from GemFast v1.8, you may find
it helpful...

*************************************************************************
* GRFBLIT.C - grf_blit() function.
*************************************************************************/

#include "gemfast.h"

HELP!

I'm using Lattice C 5.06.02 and wanted to use the MyDials from Interface
(SHIFT ...) but that version is for TURBO/PURE C,.. is their a way
of using this lib for Lattice C or is their a version availabe for Lattice C.

Has anyone an alternative like FLYDIALS, or an other RESOURCE-supporting library
for Lattice C ??? The sources of FLYDIALs or MYDIALs would do it fine, I'll adapt it
myself,...

HELP !

Contact me by EMAIL or write me:

1579. Sozobon v1.33i -- current status

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-21 19:37:12 UTC
From: ilepore@isis.cs.du.edu
Message-ID: <1992Apr21.193712.3212@mnemosyne.cs.du.edu>
Source record: 44876

I recently sent Steve Yelvington a little status report on my verson
of Sozobon C and asked him to post it here. Now I've figured out how
to post things here myself, so here's what up with the next release...

I am planning another sozobon release soon, more so now that you've sent me
more bug reports. My future releases of sozobon are going to be called
HSC (Heat and Serve C) and are going to lose all connection to the
sozobon name. After seeing what the sozo crew has done with their v2.0,
I can see that they're going in different directions than I (they're after
unix compatibility and other things I don't care about; I wanna concentrate
on usability improvements, I don't care if it'll compile under unix or not).

I've studied what sozo v2.0 did to get longer external names, and I'm
planning on hacking the same (or a compatible) method into HSC. But, it
won't be the next version, I just don't have time right now. The next
version (which'll be called HSC v1.34) will fix minor bugs (listed below)
and will have the v1.8 of gemfast in it.

HSC v1.34 minor fixes planned as of now:

- A table in LD is pre-sized to allow up to 100 modules in a library.
GemFast now has more modules than that, so the table is expanded.

- The HCC -I option is being handled wrong, I discovered. From now on
it'll search the -I paths first instead of last.

- memcpy() bug: I haven't fixed it yet, but I will for v1.34.

- If someone can educate me on the ARGV standard I'll fix STMAKE.

- There's a new tool to replace the (braindead) SZ and NM programs.

As to bug reports you sent me:

Ben Gilbert reports problems with using VDI. Offhand, they sound like
coding bugs more than vdifast.a bugs. They sound a bit reminiscent of
using the physical workstation handle directly instead of creating a
virtual screen workstation. Hard to say, but hopefully GemFast v1.8,
with it's new easy-to-use apl_vopen() function will help.

Speaking of VDI, there were some radical bugs in the bindings. I got
a nice letter from a gent in England detailing the bugs and fixes, and
they've been applied. They affected all VDI escape functions, and a few
other things as well.

Bug in fsize() -- I've never used that function, I'll look into it.

Bug in memcpy() -- I'll fix it, thanks for the detailed example.

Definition of BYTE, WORD, and LONG in TYPES.H -- ::sigh:: As a general rule, I hate using words like that to (supposedly) make code portable. I wish folks would just use short when they mean short and long when they mean long and leave the int word alone. Anyway, I'm afraid that if I change TYPES.H a lot of existing code will break, especially in dlibs. Maybe I should just document this as "something you might wanna check."

bugchk() in TOP -- I think I fixed this already, but I'll have to check my version notes to be sure. In general, I use bugchk in the same sense as VAX/VMS does: it means that somehow the program reached a point in the code that just "cannot happen" and it doesn't know what to do next. Usually it's a fatal error, but this mighta been some special case I was testing for in TOP.

dlibs - I was planning on rewriting these, but now someone has uploaded to BIX the source code for the MiNT libraries, and instead of reinventing the wheel, I'm going to investigate using them in place of dlibs to whatever degree is possible. Not in v1.34 though, the next version after that.

1580. GemFast v1.8 pre-release announcment (long)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-21 19:41:08 UTC
From: ilepore@isis.cs.du.edu
Message-ID: <1992Apr21.194108.3369@mnemosyne.cs.du.edu>
Source record: 44877

As to GemFast v1.8 -- Tonight I'm putting together a little demo program and an excerpt from the new document file, just to give folks an idea of what the new version's look-and-feel will be. The libraries will be going out to beta testers in a couple days. I recently wrote a little summary of new features for the folks on BIX, here it is:

Well, GemFast v1.8 is very near its beta release. I've dropped a few hints about things that'll be in it, and now I've been asked for more details, so I decided to put together a little summary. GemFast v1.8 has more changes and new things than any version of GemFast since v1.0. I put away the metaphorical microscope I've used in working on previous versions and added a lot of new high-level functionality.

The changes start with appl_init(), a logical starting place. It now initializes a new group of global variables which are then available for reference in your code. I found that every GEM program I write has calls all over the place to get the system desktop rectangle and other common values, so I decided to just get all the common values once and make them globally available for reference at runtime. There are also easy-to-use new interfaces that open and close VDI workstations without all the tedium.

A group of new medium- and low-level object utilities have been added. This ranges from simple things like dealing with extended object types to complex functions that implement new types of objects you can use in dialog boxes. For example, there is now a thermometer-display object type, G_THERMO, which lets you easily use this type of progress indicator in your dialogs. There are also several new types of buttons, including CUA/Windows3 style buttons and rounded-corner radio buttons.

Some miscellanious changes were made to extend the functionality of existing AES functions. Certain aspects of the GEM GUI make it hard to write 'blackbox' library routines which are independant of the current state of the main applicaton. For example, GEM doesn't allow you to query the current shape of the mouse cursor, so a library routine can't temporarily change the mouse to an arrow then change it back. Under v1.8, the graf_mouse() call returns the old cursor shape when you set a new shape. Likewise, the standard wind_update() function isn't so hot: any number of wind_update(BEG_UPDATE) calls can be cancelled by a single END_UPDATE. Now wind_update() works like turning the mouse on and off; if you made 3 BEG_UPDATE calls, you'll need 3 END_UPDATE calls to actually release control of the window semaphore. This lets library routines aquire and release the window and mouse semaphores without disturbing the state of the main application.

There are new high-level functions for blitting areas of the screen easily, using your memory buffer or allocating one for you. There are some new rectangle calculation functions, such as creating a scaled copy of a rectangle, confining a rectangle within the boundaries of another, etc.

But by far the biggest changes are in the forms library. The old forms library consisted of a single function, frm_dsdial(). Now there are 25 functions, and I'm still thinking of new ones on a daily basis. The heart of the new forms library is the frm_dialog() function, which conducts dialogs for you. Basically, it does the form_dial(), objc_draw(), form_do(), and so on. But, it does a lot of extra stuff along the way, including handling the following options for you:

- Saving and restoring the screen via blits instead of redraw messages.
- Dialog boxes are moveable; the user can drag them around to anywhere on the screen.
- The mouse can be forced to an arrow shape during the dialog then restored to its prior shape.
- The dialog can be centered within the screen, or made to pop up centered over the the current mouse location.
- It supports both standard dialogs and menu dialogs, in which the objects highlight as the mouse crosses them, like dropdown menus do.

Here's a summary of the new dialog functions:

The functions which help you conduct your own dialogs are:

frm_confine Confines dialog to rectangular area.
frm_defaults Sets default options.
frm_dialog Conducts your standard dialog.
frm_menu Conducts popup menu dialog using your object tree.
frm_eflag Reports error made by user in a dialog.
frm_enableblit Enables screen save/restore via blit.
frm_mkmoveable Makes your dialog moveable.
frm_desktop Installs your custom desktop.
frm_sizes Calculates dialog's on-screen sizes.

The basic dynamic dialogs are:

frm_dsdialog Automatic text dialog - hard to use.
frm_dsmenu Automatic menu dialog - hard to use.
frm_nldialog Automatic text dialog - easier to use.
frm_nlmenu Automatic menu dialog - easier to use.
frm_printf Formatted text dialog, like printf().
frm_error Formatted error reporting.
frm_vprintf Alternate form of frm_printf.
frm_verror Alternate form of frm_error.
frm_progress Formatted text with thermometer progress display.

The quick-and-easy dynamic dialogs are:

frm_qchoice Formatted text and choice of 5 buttons.
frm_qerror Formatted error reporting.

frm_qmenu Automatic popup menu (like dropdown in a box).
frm_qtext Formatted text display.
frm_question Formatted yes/no question.

The other big change in GemFast v1.8 is the documentation, it's been completely rewritten. It now resembles the library reference manual from a commercial compiler or graphics library. It includes cross references to related functions, a complete table of contents, a quick-reference chapter and detailed explanations of functions in separate chapters, and in general it's easier to use. Printed out, it's 100+ pages long; there's certainly no lack of information on how the functions really work. ::grin::

As usual, v1.8 will be released with full source code. I've taken major steps towards portability, but it's not there yet. I hope for v1.9 to be the true portability release, with source code that will compile on all ST C compilers, including GNU and other 32-bit compilers.

thanx for the tip (everyone) on the NULL ptr for MFDB fd_addr field. i alluded to this in my post and several people sent me this info. it even works, too... :-). now that i think of it, the old Sybex GEM book must have shown this since the PC does not have a Physbase in its BIOS.

i think if i have time, i will add my own popup/ladder menu system to mgif (now called gemmgif :-). i wrote that ages ago and never really used it. now i can...

Pass 0, as the destination pointer, then the VDI fill in all the physical
screen parameters.

Note that the you can't copy between standard and device dependend forms.
they have to be both in standard- or both device dependend- format.

>I do when it won't compile in 4 megs any more?

A looooooong time. 2-2.5 meg has always been a bit tight with GCC. 4 megs would be fine, since you'd have about 5 times as much free memory. So you could compile something about 5 times the size of Nethack without running into any troubles.

>Are people out there compiling hefty C++ code with G++ on their ST's?

Providing you don't write MONOLITHIC code, you should be able to create HUGE programs, since the linker is quite small. You only need the memory when compiling large files, especially those with large *functions* in them. Since G++ encourages more modular coding than GCC (C++ vs. C), you shouldn't have any troubles.

>I'd hate to think that such a powerful tool has been relegated to

> should the drive speed be?
> -Steve <selick@csa.bu.edu>
>

Some of the older drives had speed adjustments, but not the newer ones,
they use a ceramic resonator for the clock but I have shifted the clock
speed on a drive by changing a tuning capacitor, but then that was not
a Atari drive, but a Amiga one..

!!! speed must be 300 rpm +/- 2% !!!.

You can find a pot on some of the drives this is for Index timing,
so be carefull with it..

1587. proper way of doing things under MiNT

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-22 06:17:36 UTC
From: boender@dutiws.tudelft.nl
Message-ID: <1213@dutiws.tudelft.nl>
Source record: 44884

```
Hi all,
I have a few questions about the proper usage of MiNT and its calls.

1) File locking
What is the proper way of doing file locking on MiNT? I want to know what to
do if a lock fails (just wait and retry? how often?), how long a time a lock
may be kept and if I must do a Fcntl(F_GETLK) before a Fcntl(F_SETLK).

2) Reading input without busy waiting
The TOS single-process way of reading input is:
while (!Cconis())
;
retval = Crawcin();

Now, under MiNT I could do:
Fselect(wait until keyboard input);
retval = Crawcin(); /* or some such call */
or
retval = Fgetchar(from keyboard);
or
Fselect(wait until keyboard input);
retval = Fgetchar(from keyboard);
What's the proper MiNT way?

3) Getting resource usage for the whole system
How can I write a performance monitor showing CPU usage (like xload)?
Do I have to read kernel stuff or is there a proper system call?

All answers will be appreciated.
Thanks in advance,
Hildo Biersma (boender@dutiws.tudelft.nl)
(biersma@dutikos.tudelft.nl)

1589. What is the latest version of Pure (Turbo) C.

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-22 10:04:03 UTC
From: geert@ccsds.ahold.nl
Message-ID: <3282@ahds.ahold.nl>
Source record: 44886
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

While looking at the news, I saw some postings about Pure C
for the atari-st. I am a proud owner of Turbo C.
What is the version of Pure (Turbo) C now? The latest version
I know and have is 2.03, and was then named Turbo C.
If there exists a newer one, what are the enhancements made
to the 2.03 version, and how much is the update price.

Also, for those who are using the bgi interfaces of Turbo C2.03,
I have the following question.

Is it possible to combine bgi with gem? When I use the bgi interface,
the mouse pointer disappear. You can switch it back on. But I discovered
problems using a menubar or a form with bgi being actif.
Mostly the program crashed when I enabled something of GEM.
How is it possible to mix both gem and bgi? Hopely someone will help
me with this.

Thanks in advance.

Just a couple of words of warning if you're thinking of using this method
to run the loaded program several times wihtout having to load it from disk
each time. Firstly, and obviously, if the program contains self modifying
code, then its anyone's guess whether it will fail in some weird and wonderful
way or not. Secondly, You'll need to store a copy of the DATA segment somewhere
before you first run it, and then restore it every time you run the program
again. Thirdly, you'll probably want to clear the BSS segment each time you
run it. Further top point 2, I've seen several ST programs that don't have
seperate DATA segments, and hence its impossible to store them. To be really
safe, I guess you'd have to keep two copies of the entire program in memory,
and copy the backup onto the executable image every time you run it.

1592. Mark William's C (old version) fseek() problem?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-22 13:45:24 UTC
From: CADS_COLE@GALLUA.BITNET
Message-ID: <1992Apr22.084524.1@gallua>
Source record: 44889
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Greetings from the void,

I've got an ancient (relativly speaking), ST with an equally ancient TOS and Mark Williams C. The copyright on the C book says 1986. Unfortunately, it's not mine, and it's the end of the semester, so I have neither the time nor the motivation to buy upgrades for it.

Now, the problem: Is there something wrong with the fseek()? Here's a fragment of a program that runs correctly on a VAX and an Amiga 3000 with Matt Dillon's DICE. The whole program is 319 lines long.

```
(void) fseek(fin,0L,2);
dumpsize = ftell(fin);
head = NULL;
if ((head = lcalloc(dumpsize,1L)) == NULL)
{
printf("The memory allocation failed... Aborting.\n");
exit();
}
(void) fseek(fin,0L,0);
(void) fread(head,dumpsize,1,fin);
fclose(fin);
printf("%ld bytes read from %s\n",dumpsize,fid);
```

This results in 3 bombs. Dropping some printf's in to see where things failed, it appears to happen just after the second fseek(), when it attempts the read. This suggests to me that the fseek(fin,0L,0) is not returning me to the start of the file, as it claims in the book. (I tried using SEEK_SET or was it SET_SEEK? In either the #define isn't there for this version of Mark Williams. It does exist for the VAX and the Amiga C's.)

>be using MiNT + Bash...

The scary thing is that these GNU binaries keep getting fatter and
fatter. Soon you won't be able to compile hello.cc on a maxed-out (4
meg) ST! I just had a hell of a time getting Nethack pl10 to compile
on my 2.5 meg ST with GCC 1.40 -- I had to disable EVERYTHING, even
FOLDXXX, to have enough memory. (Switching to the 20K Sozobon make.ttp
instead of the 120K gnumake was also essential.)

I'm afraid to start using G++ for a sizeable project because what will
I do when it won't compile in 4 megs any more? (Buy a TT? Not for 1/3
the price of a car.) Is this a realistic concern? Are people out
there compiling hefty C++ code with G++ on their ST's? I'd hate to
think that such a powerful tool has been relegated to "toy" status due
to memory limitations.

Dave Baggett
dmb@wam.umd.edu

Does GCC/G++ actually run on a 4MB ST?? I can get the GCC part to compile "hello.c"
but the G++ part just exits very quickly when it attempts to run the
gcc-cp1+.ttp program. I have this feeling that I wasted a bunch of time transferring
files, cleaning up my hard disk, and installing GCC/G++ 2.1 only to find out its
not going to work on a 4MB ST. Anybody actually get this monster to run on a ST??

> Can a program be run from a DA

A text-mode TOS or TTP type program can be run from a DA without much trouble at all. (Troubles might occur if the program steals vectors and TSRs, or other weird stuff like that.) A GEM-using .PRG can't be run from a DA, however, because of conflicts with the main application and GEM's nasty lack of reentrancy. In general, whenever a GEM application (DA or program) fires up another GEM application (the 'subprogram'), then the subprogram will get a gl_apid value which is the same as the main program that started it. This causes problems with the message queue, the state of the wind_update() semaphores, and a variety of other nasty things that are hard to hack around.

1596. serial using C

warwick> Since G++ encourages more modular coding than GCC (C++ vs.
warwick> C), you shouldn't have any troubles.

I doubt if you can avoid troubles: libg++ is a bad example as it does
not heavily use inheritance, one of the main advantages and
applications of c++. Try to compile the NIHCL library which is
smalltalk like. I didn't try, but I guess it might well exceed the 4
mb limit although it is not monolithic at all: deep inheritance, i.e.
well structured c++ code, consumes lots of memory. Programs I compile
on a sun with 8 MB cause it to trash heavily.

Hello,

I try this as an easy way to find out which sozobon C version I should ftp. There are lots.. are they all the same, is one better... Anyway I have 2.5 Mb internal memory (since today) so I can handle some bigger version, if there's a difference. I prefer that one too (because I think bigger means more possibilities, more speed, maybe not more of both of them..) Is there some documentation included? If not, somewhere? And (for my own health I should not ask this) how can I use the machine language?

So I only have questions, could you please send your answers to my email adress: bert@cs.vu.nl

Thanks, Bert.

The documents says MultiTOS will run on a 020, so there should
be no problem. They (the documents) also say that if there's a
demand for it they will make it work on the 010 too. I suppose
the only work needed to take the 000 version to a 010 version
is a rewriting of the stack-handler and a small patch for the
SR-problems. We'll see when they finally relese it (the thing
I'm referring too is a beta-version).

I don't have my copy of MWC loaded on my hard disk to check, but I
suspect that your problem is not in fseek but rather in fread. I
think you're running afoul of some peculiarities of MWC that relate
to object size.

The MWC fread function is documented like so:

fread( char *buffer; unsigned size; unsigned n; FILE *fp )
^^^^^^^^^^^^^^

I assume that your dumpsize variable is a long.

As a result, you're pushing a 32-bit value on the stack where the
function expects to find a 16-bit value. This screws up the n and fp
arguments. When the fread function dereferences the file pointer,
it gets nonsense, and your program goes kablooey.

Now that I look at it, I think the Mark Williams Co. did a weird
thing by making fread and fwrite work with unsigned args while
```

fseek and ftell work with longs.

Hans, I'm puzzled. You shouldn't need to mess with the CTS line; that should be handled by TOS (or by whatever serial port fixup software you are running, such as TurboCTS). All you need to do is read from and write to the aux port using GEMDOS or (preferably) BIOS.

The Rsconf() function will let you turn RTS/CTS flow control on or off.

If you are really looking for code to raise or lower DTR and check the CD line, say so and I'll dig it up.

There is Zmodem source code on atari.archive.umich.edu, but I think it assumes that you have Mark Williams C. Good luck. Looking at the Zmodem code gives me headaches.

> some assistance. Thank you.

Hmmm...here's some info excerpted from Abacus' disk drives book.

On disk, it's the file header, program with data field, symbol table (if present), and relocation data (if present)
Header first:
2 bytes, = $601a (BRA $1a)
4 bytes, the length of the program segment
4 bytes, length of the data segment
4 bytes, length of the bss
4 bytes, length of the symbol table
10 bytes, reserved, should all be zero (unless...fastload bit? TT RAM?)
Immediately after is the program. "All addresses which the program uses are set up so that the start of the program is taken as address zero"
The relocation table contains the distances between the longwords which must be relocated. The first longword specifies the offset of the first longword needing changed, starting from the beginning of the program. All subsequent values in the reloc table specify offsets from the previous value; a linked list of values, if you will. If the next longword needing relocated is too far (>254) to be expressed properly, the value 1 gets inserted until the distance is <255.

Is that what you wanted, or did you want the format of a program currently loaded in memory?

> it gets nonsense, and your program goes kablooey.

I was dozing. MWC pushes arguments from right to left, so it is the buffer
pointer that gets hosed, not the file pointer. Same result, though.

Note that C does not specify the order in which args are pushed onto
the stack, or even whether a stack is employed.

The Z-Modem code is not PD, you have to by it, it costs from memory
some $92us, I did read some thing about this from the Author
on a Z-Modem Fido feed..

>Does anyone see anything obvious? Thanx again.

Maybe it's a stupid remark, but I can't see how you can determine from the length of the environ[0] string that you're running as a GEM-application or a TOS-application. As far as I know there is no standard way to determine this (although a friend of mine once made a Turbo-C hack that works reliable). You should know the name of your program in order to know if it's GEM or not. Programs ending as .PRG or .APP are GEM; .TOS and .TTP are TOS - but what if the user is allowed to change the program-extension and start it from a shell - in which case you're (in general) not able to locate your own program and find out its name (-this is precisely what my TC-hack makes possiblle, though :)

Your code supposes (as far as I understand) that strlen(environ[0])==5 signals GEM-use... This can't be correct - what if one doesn't use an environment at all? The length of the env-strings has in principle nothing to do with the difference between TOS and GEM.

BTW: Your GEM_Init code is just the normal way of installing and initalizing a virtual graphic workstation. This should only be done when you're running as a .PRG or .APP, otherwise the machine will crash. The same applies of course to the use of menus, dialogs and all the other GEM-stuff.

1608. WANTED: How to dump all variables

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-23 12:16:47 UTC
From: xxbrent@convx1.lerc.nasa.gov
Message-ID: <1992Apr23.121647.20678@eagle.lerc.nasa.gov>
Source record: 44805

Is there a generic method for displaying all variables upon error exit, using GFA Basic under GEM? I am posting this for my father-in-law, so I do not have any documentation. Ideally, there would be a GFA Basic command "display-all-variables-and-contents", but if not, perhaps someone knows a way (or has code) to read a symbol table, then display variable names and contents using it.

Any ideas or suggestions would be appreciated.

Thank you in advance.

Yes, that strikes me as odd too.

> As far as I know there is no standard way to determine this
>(although a friend of mine once made a Turbo-C hack that works reliable). You
>should know the name of your program in order to know if it's GEM or not.

Hmm. That's not true either: if I take a shell - say, 'shell' - which I start
as 'shell.tos', and I give the command 'life' the life program - being called
life.prg - will be fooled into thinking it is running as a GEM program if it
examines its own name.
For the same reason, you also cannot assume that you're a TOS program only
because you received parameters.

IMHO, it's easier than all this suggests: if you want to make sure you have AES
functions, then ask so. If you're not allowed to appl_init won't give your app
a handle. Do you need VDI functions? Open a [virtual] workstation, if you don't
get a handle: no VDI. Easy.

>it appears to happen just after the second fseek(), when it attempts the read.
>...
My guess is that you do not have a declaration for lcalloc; so it defaults to
int. As MWC uses 16-bit ints, the 'head' variable only gets 16-bits of the
address, and the top 16-bits will be set to all zeros or all ones (sign
extension). Hence, head is likely to contain an invalid address, so
you get the address error (3 bombs).

Try adding a "void *lcalloc();" declaration, or find a header that
has the declaration for you. This is a common bug in C code with
16-bit ints.

>going to reiterate my question one last time: would
>some kind soul _please_ describe the format of an
>executable file, especially (but not exclusively)
>relocation information? I would _really_ appreciate
>some assistance. Thank you.

An executable program file (.PRG, .TOS, .TTP) is divided into four segments. These segments are the file header, program with data field, symbol table, and relocation data.

file header.
byte # contents
$00,$01 $601A (bra $+1A) branch to program start
$02-$05 Length of the program segment (text)
$06-$09 Length of the data segment (data)
$0A-$0D Length of the additional storage segment (bss)
$0E-$11 Length of the symbol table
$12-$1B 00,Reserved
$1A Program start address

The text, data and bss segments are those segments defined in standard 68000 assemblers.

Each entry in the symbol table is seven words long and contains the name, type and value of the symbol.
byte contents
$0-$7 symbol name
$8-$9 Symbol type relocatable, global or external
$A-$C Value (address, register number, direct value etc).

The symbol table may be 0 length if the symbols have not been included.

Following the symbol table is the relocation table, this table contains the distances between the longwords which must be relocated. The first longword in this table specifies the offset of the first longword to be changed from the start of the program. After this bytes are used whose value gives the distance from the current longword to the next longword to be changed. If the distance is greater than 254, bytes of value 1 will be inserted untill the distance is less than 255. The first byte to contain 0 indicates the end of the relocation table.

When the program is loaded into memory the relocation table is no longer availiable, this means that relocation of a memory image of the program is

not possible (unless of course you write it pc relative!). The memory image is not the same as the file image.

hope this is usefull.

regards dennis

^^^^^^^^^^^^^^^^^^^^^^^^

|> (void) fread(head,dumpsize,1,fin);
|> fclose(fin);
|> printf("%ld bytes read from %s\n",dumpsize,fid);
```

At first try 'rewind(fin)' instead of 'fseek(..., SEEK_SET)'
The seek modes are defined as SEEK_SET, SEEK_CUR and SEEK_END,
e.g. 0,1,2, (or was it for lseek() only).

I think it could be important to print out 'dumpsize' after the
first fseek() and ftell(). It _must_ be the length of fin (is
it on my Unix system).

Or try an offset of 1L in your first fseek().

Then check the structure 'fin' and all it's contents, especially
the current file position, after each fseek() operation. Do it
with a ftell() call or with fin->fpos (?) or in any other way.

Then decrease dumpsize before fread() to see if fread() fails.

But I think one of your library functions has a bug. (I use
gcc and Turbo C, so I don't have any experience with your
compiler) ap.

Steve> This is interesting; I hadn't noticed it, and I don't know what Ian
Steve> has done to the argument-parsing code, since I don't have sources.

Steve> I'll record this as an apparent bug, with reservations (see below).

Concerning Sozobon 2.0 I have noticed the same problem. When
debugging I noticed that the basepage cmdlin contains the arguments
but not the program name, so no argv[0]. The startup code explicitly
sets argv[0] to "".

So I guess some extended argument passing scheme must be used, such as
ARGV or XARG. Is there a more intelligent startup for Sozobon?

Bye,

1616. Last Two Clusters Unavaiable Feature

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-23 16:35:17 UTC
From: ralph@laas.fr
Message-ID: <RALPH.92Apr23183517@orion.laas.fr>
Source record: 44813

I know that this subject has been hashed around in one of the Atari newsgroups or maybe even the info-atari mailing list of yore, so excuses if this bores you.

Background: TOS does not let you write into the last two clusters of a floppy disk. I understand that this *error* from TOS 1.0 and 1.2 was kept in the newer versions of TOS in order to provide backwards compatibility. Thus, now it is a feature! It seems that the last two clusters are even unavailable on hard drives, also!

The reason for this posting is to ask *why*? Is the only problem if one would create a 1 or 2 cluster file on precisely these 2 clusters? Would this file be invisible from TOS?

The reason I reopen this subject, is the problem when one transfers files between STs and PCs or SPARCs. The latter machines gladly fill up the last two clusters. I have noticed on my machine (running TOS 1.2) that if a file runs over these last 2 clusters, it is *still* readable by TOS. I tested this on some gcc 2.1 zoo archives which completely filled up some floppies; they tested out and extracted all okay!

So what gives? I would appreciate any corrections in the case that there is mis-information in the above.

Thanks,

I confess, I'm in way over my head with this stuff. I started out writing a simple C program after starting msh. While I was in msh it worked fine. When I exited and tried to run the same program from whatever the machine boots up with (GEM?), the program bombed. So, I assumed, based on a few sketchy examples, that I needed this init stuff. Then I found it worked from GEM(?) but not from within msh... All I want to do is get it working when I click on the damn filename with the mouse, or type the damn filename into msh.

It's not meant to be incredibly portable and general, so I looked through the Mark Williams Lexicon, and found an example that showed how to read the msh PATH= string via environ. A few preliminary tests showed me an empty path string when running from GEM and a considerably longer one from within msh (because the profile file defines it). And msh cleans up after itself when it exits, undefining PATH again, giving me a string "PATH="... 5 bytes long.

Oh, when I run from msh, I want the program to take arguments on the command line. Basically, I prefer to run it from msh. But other people don't want to play click-on-click-on-click-on... to get to msh. They want to just click on my program and have it go.

(I created the executable by typing: "cc program.c" to msh, and it creates program.prg. Then when I added the GEM stuff, it wouldn't link, so I switched to "cc -VGEM program.c" and again, it creates progam.prg.)

Now the hard part: I was hoping to get it working by noon, Friday. Such is life.

So, let me ask the question a different way: Why won't the straight, standard, non-Atari code work when I double-click on the program name, and what's the *minimum* amount of junk necessary to make it work, without destroying the ability to type in the program name from msh? (I can even live with removing the arguments on the command line.) Keep in mind, I don't know shit about Atari's.

Thanx once again.

NO NO NO NO! When programs run from *my* desktop, they have a nice long PATH= string. This will be true for anyone using my GEMENV program that brings environment variable support to the GEM desktop. (And if you're a desktop user, you *should* be using GEMENV!)

I am surprised to see people talking about confidential information from the MultiTOS release for developers. Be sure that Atari knows the difference between 68000, 68010, 68020 and 68030. And please note, that MiNT 0.94 already supports the 68010 (and MultiTOS uses MiNT as kernel).

Almost correct, the text segment starts at 0x1C .
An alternative description is the function below that
reads and relocates text and data:

typedef struct {
short magic;
long textLength,
dataLength,
bssLength,
symbolTableLength;
char reserved[10];
} headerType;

/* sizeof(header_type) == 28 */
/* magic == 0x601A */

/* the relocation table follows the symbol table upto the special value
EORELTAB */

typedef struct {
char name[8];
short kind;
long value;
} symbol;

/* special relocation values: */
#define EORELTAB 0
```

```
#define EXTENSION 1

load_and_relocate(fd)
int fd;
{
extern char *lalloc();
headerType header;
long valueToAdd;
char *textAndData;
long currentOffset;
unsigned char relVal;

fread(fd,&header,sizeof(header));
textAndData = lalloc(header.textLength + header.dataLength);
read(fd, textAndData, header.textLength + header.dataLength);

/* the program in the file has absolute addresses as if it */
/* were loaded at address 0, so add the start of the text */
/* to the absolute addresses. */

valueToAdd = (long) textAndData;

/* skip the symbol table */

lseek(fd, header.symbolTableLength, SEEK_CUR);

/* the relocation table starts with a single long which is the */
/* offset of the first address to relocate. The rest of the */
/* table are unsigned char's, offsets from the previous address*/

read(fd, &currentOffset, sizeof(long));
*(long*)(textAndData+currentOffset) += valueToAdd;

read(fd, &relVal, 1);
while (relVal != EORELTAB) {
while (relVal == EXTENSION) {
currentOffset += 254;
read(fd, &relVal, 1);
}
currentOffset += relVal;
*(long*)(textAndData+currentOffset) += valueToAdd;
read(fd, &relVal, 1);
}

free(textAndData); /* :-) */
}
```

1625. Problem with GDOS and gcc revisited

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-24 14:17:25 UTC
From: D.M.Johnson@newcastle.ac.uk
Message-ID: <1992Apr24.141725.27734@newcastle.ac.uk>
Source record: 44822

I asked this question before and implemented the corrections to the code that I had produced. As a result the code I have got should work but doesn't. The problem is that AMCGDOS reports an error when I open a virtual workstation using gcc 1.40 and the gemlib on atari.archive.

The group I have been talking with are at a loss so here are a cuople of questions so I can track the problem down.

What is the latest version of AMCGDOS (I think I have it but am not sure)

Is the gemlib in the directory in A.A. the latest version?

The most likely problem is that there is a bug in the gemlib. As a desperate measure I descended in the world of Assembler (I not too good in this area). The example code provided with Devpacs using the Hisoft macros worked with out a problem, I just have to understand the macros. However a program from ST Format on how to print usign a printer driver reported the error and then printed on the printer. This leads me to believe that there is a bug in either AMCGDOS or the gemlib (most likely)
Anyone got any suggestions

Dave Johnson

This describes one of many various formats in use. There are not
necessarily compatible. To see executable file format in action study
sources for loader (Sozobon C, gcc) or for debugger (szadb 2.1 will
give you a good idea how to handle multiple symbol table formats
in the same program).

1628. Solved. (Was: Mark William's C fseek() problem?)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-24 14:54:13 UTC
From: CADS_COLE@GALLUA.BITNET
Message-ID: <1992Apr24.095413.1@gallua>
Source record: 44825
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st,comp.lang.c

As pointed out by several people on these lists, the problem was not with my fseek, but with my fread that followed it. If anything, the bug is an inconsistency between Mark William's C's ftell and fread. ftell is defined as returning a long, yet fread expects an int. So, when I fed fread a long dumpsize (as returned by ftell), everything went haywire.

Thanx all.

Brent, unless you are using GFA BASIC version 2.0 (which was made widely available when published on Antic's Start magazine disk), why don't you have the documentation?

And if you are using 2.0, why don't you stop punishing yourself and upgrade to 3.5? There is _no_ comparison to the power, speed & capabilities here! In the US, call GFA Software Technologies at 1-800-766-6GFA for upgrade info.

The command you are looking for is called DUMP:
DUMP ! dumps all var values and the dims of arrays
DUMP "a" ! dumps only vars and arrays that begin with "a"
DUMP ":" ! lists all labels
DUMP "@" ! lists all procedures and functions

It's not as good as something like XREF but hey, it's in there. This may be a 3.0+ specific command, I don't recall.

If you _are_ using any version higher than 2.0, this means you are likely a software pirate (aka, thief). Kindly disregard the DUMP instructions above, confess your sins and pay the upgrade fee.

If you are a _legitimate_ user..... never mind. :)

> Watch out for the 68010! The current(?) version of MultiTOS (Atari's new
> multitasking (taskswitching) OS) does NOT work on the 68010 :-(

(1) MultiTOS is a true multitasking OS; it isn't just task switching.

(2) MiNT runs on a 68010 now. MultiTOS is based on MiNT. Draw your own
conclusions...

(Of course, exactly what goes into the final version of MultiTOS is entirely
Atari's decision, but I wouldn't expect them to *remove* 68010 support :-)).

> may be kept and if I must do a Fcntl(F_GETLK) before a Fcntl(F_SETLK).

If a lock fails, you should wait and try again. How long to wait, and how many times to retry, is up to you -- it really depends on the application.

> 2) Reading input without busy waiting
> The TOS single-process way of reading input is:
> while (!Cconis())
> ;
> retval = Crawcin();

I think just plain

```
retval = Crawcin();
```

is better if you want to avoid busy-waiting (since the "while" loop above is, in fact, busy waiting!). This also works fine under MiNT.

If you have a lot of data to read, the Fread() system call is *much* more efficient under MiNT than Crawcin() or any other single-character input routines. There are Fcntl() options to make Fread return immediately if no data is available, and also to control how Fread behaves (assuming that you've done Pdomain(1) to get into the MiNT domain).

> 3) Getting resource usage for the whole system
> How can I write a performance monitor showing CPU usage (like xload)?
> Do I have to read kernel stuff or is there a proper system call?

Use Dopendir/Dreaddir/Dclosedir (or Fsfirst/Fsnext) on the directory U:\PROC to find what processes are running. Use Fopen() on the "files" in that directory, along with various Fcntl's, to get information about the process' resource usages. See the source code for "ps" or "top" for an example. (The files ps.c and top.c may be found in mntutl93.zoo on atari.archive.umich.edu.)

On the theory that an example is the best sort of explanation...

FTP to atari.archive.umich.edu (or use the mail server) and get the file /atari/mint/mint094s.zoo. In the file "mem.c" are MiNT's functions for loading and executing TOS executable files. (The functions are called "load_region" and "exec_region", I think -- it's been a while since I've had to work on that part of the code :-).

From: wr@bara.oche.de
Message-ID: <H.lNGJEfbPnEk@bara.oche.de>
Source record: 44833

Hi all,

Now there are those VDI functions, vq_gdos and vq_vgdos, that check if
gdos is installed and if it is, determine its version number. But what
does the version number really mean? PureC's online help gives the numbers
of FSMGDOS and FONTGDOS, but does anyone know the numbers returned when
using other gdosses, like NVDI, AMCGDOS, the original Atari GDOS, etc.?
Or is there some hidden magic in the bits of the version number?

Thanks for any help...

1636. What does MiNT do to TOS country info?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-24 20:33:48 UTC
From: wr@bara.oche.de
Message-ID: <H.47b75nSEWu2@bara.oche.de>
Source record: 44832

Hi all,

what does MiNT do to the TOS country number in the OS system header?
I use the following to print the TOS version number and country
(where syshdr is a pointer to the SYSHDR structure):

```
int vers,cntry;
static char *TosCntry[]=
{
"USA","FRG","FRA","UK" ,"SPA","ITA","SWE",
"SWF","SWG","TUR","FIN","NOR","DEN","SAU","HOL"
};

vers = syshdr->os_version;
cntry = (syshdr->os_palmode)>>1;

printf("TOS Version %x.%02x (%s)\n",vers>>8,vers&0xff,
cntry<15 ? TosCntry[cntry] : "???");
```

This prints "TOS Version 1.04 (FRG)" when called without MiNT and
"TOS Version 1.04 (???)" when MiNT is installed. Trying cntry&0xf
gave me NOR, so there are not just some extra bits used after the
country number...

How do I get the correct country number both with and without MiNT?

Thanks for any help

I am in the market for and engagement ring and I am in
desparate need of money. If you are interested in
upgrading your system or buying a TT, make me an offer
on my TT, I might be desperate enough to take it...

TT030 Computer w/ 4MB ST RAM
50MB internal hard drive
PTC1426 color monitor
Cordless mouse
2400 Baud Supra Modem
any pd software on my harddrive...

All for the low asking price of $2100obo (excluding shipping).

Besides the above, you get all the other TT features like VME, LAN,
multiple serial ports, higher rez, etc.

Thanks,

Richard Hall

>I think the answers should be yes,yes,no,no BUT I'm just covering all bases..
>

1) As far as I know the SST does not work on any STe currently, just on normal ST's and Megas (someone help me here -- I know the TinyTurbo 030 works on all ST's, is the SST just for the Mega ST?)

2) The Mega STe's and the TT both have a VME bus which allows the addition of networking, graphics, other standard cards with the appropriate software to match it. I assume when Dave gets the Megatalk in production that the Mega STe version will be VME bus, this is the most logical way to do it -- also, you should be able to find VME networking cards not Atari specific, problem now is the software to drive the thing. If you are saying does the Mega STe have the same bus as the Mega ST, the answer is no, it doesn't. However, like I said, it has VME which is even better. :-)

3) I am 99.9% sure Spectre GCR has no problems with the Mega STe's, as I have been to two different dealers where they had a Mega STe with a Spectre GCR cartridge plugged into it, working just great (it really speeds along with the 16MHz and the cache enabled), they had a SLM804 hooked up too so I don't think there are any problems.

4) I have no idea, I'm still a lame floppy user with TOS 1.0 (soon to be TT030 I hope when I get out of school), so I have no idea how the ICD adapter will interfere or connect to the Megatalk board.

So, it looks like the answers are no,yes,yes,and who knows????

!
!>BTW: Your GEM_Init code is just the normal way of installing and initalizing a
!>virtual graphic workstation. This should only be done when you're running as a
!>.PRG or .APP, otherwise the machine will crash. The same applies of course to
!>the use of menus, dialogs and all the other GEM-stuff.
!
! Ummm, that's wrong. I quite frequently use VDI drawing and blitting in
!TOS and TTP programs, there's absolutely no reason why you shouldn't. For
!that matter, you can even use appl_init() followed by any other AES calls
!in a TOS or TPP program without crashing the system, but the mosue won't
!be active and there'll be no system desktop under your program so redraws
!will be a bit wrong. But it certainly doesn't crash the machine.

But this sounds quite dirty, because there is a way to start a shell
COMMAND.PRG before GEM/AES & VDI) is not installed (I.e starting a shell
instead of Gem.prg from mint.cnf !). In this case the Programm
will crash, due to some unsetted trap's (should at least trap #2)
What you might use is Linea in Your program (BTW this is dirty too).

Actually, for MWC you'd probably better make it "char *lcalloc();"; I don't
think MWC groks (void *)'s.

1646. questions about char *getdirentry()

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-25 16:05:02 UTC
From: jhm@anansi.UUCP
Message-ID: <H.HuxN2dm4A_o@anansi.UUCP>
Source record: 44643

I've been playing with different UUCP systems, and I've just tried to compile David 'Orc' Parson's "bauble" UUCP system using the mint libraries Scott Bingham put on atari.archive (compiled with Sozobon -- sorry, HSC -- 1.33). I've fixed most of the minor typos and I'm running into a problem with the char *getdirentry() call.

Mainly, the mint libraries don't have it, or they use a different name.

It looks like the call searches a directory and returns the next directory entry matching a string, kind of like an Fsfirst()-Fsnext() combination, returning NULL when the list is exhausted. I might be able to write one (I'm not very good with C), but first I thought I'd check the accumulated wisdom of the net. Does someone have source for Orc's version of the call or something similar?

Sample call from uuto.c follows:

```
for (fn=getdirentry("*.x"); fn; fn=getdirentry((char *)0))
if (workfile=fopen(fn, "r")) {
execute(workfile);
fclose(workfile);
remove(fn);
}
```

The reason I'm looking at this over Rodney's UUCP or Hermes is that bauble implements multiple send-expect sequences, including the ability to send breaks for logging in, a highly-useful thing with my UUCP connection. Code in C doesn't hurt, since that will run under MiNT more reliably.

I appreciate any help. If you think it's useful, post the result, or mail it to me at either of:

i>will be a bit wrong. But it certainly doesn't crash the machine.
Wrong. When you make an appl_init in TOS programs, you have to make an appl_exit, right?
But appl_exit send AC_CLOSE messages to all accessories and causes them to forget all windows, allocated memory and open files. Accs have to behave this way on AC_CLOSE.

Are you running it on a TT or MSTE/ST? Calamus SL is optimzed for TT,
and it has the fastest vector printer drivers available for TT...
How much memory does your Atari have?

Well, we let the cat out of the bag on BIX and Compuserve already, so
we might as well here too: we are working on a version of
Comeau C++ 3.0 With Templates for the Atari. Re this issue, it should
work fine even with a 2 Meg system.

>Providing you don't write MONOLITHIC code, you should be able to create HUGE
>programs, since the linker is quite small. You only need the memory when
>compiling large files, especially those with large *functions* in them.
>Since G++ encourages more modular coding than GCC (C++ vs. C), you shouldn't
>have any troubles.

Yes and no. Yes, in that C++ has the potential of allowing one to write
more modular (and then some) code. No, in that, there are typically issues
like greater use of header files, inline function visibility, and so on.
Plus realized that as the size of every ANSI C compiler doubled
over the size of thier equivalent K&R counterparts, the size of
C++ compilers are double those of the ANSI C compilers.

Anyway, back to Comeau C++: we very much enjoy having our command line
driver to be a shell script, or a rexx script, or some cli kinda thingie.
However after much internal discussion, discussion with others, and discussion
on BIX and Compuserve, it appears that there does not seem to be any
widespread enough language or product for this. Just striving for one last
double check: but is this analysis correct?

Usage of VDI without AES is illegal under MultiTOS??? Sounds to me like
MultiTOS is broken. But, breaking existing applications, where those
applications have jumped through hoops already to follow the rules that
Atari once said were cast in stone, is nothing new for Atari Corp. ::sigh::

But, that sounds to me like you can't open a VDI workstation without
doing an appl_init(). And, in my experience so far at least, you can
do an appl_init() from a TOS or TPP program without any problem. The
TOS or TTP filetype only tells the shell (or desktop) how to set up the
screen and mouse visually, it says nothing about whether the program
actually uses AES or VDI services. If Atari has changed *that* too,
well, again, ::sigh::./

Surely to open a VDI workstation you first need the physical (AES) screen handle which is obtained from graf_handle(...). Since this is an AES call appl_init() should be called first. What is your code for opening a VDI workstation?
Sorry if this has already been discussed, but I missed the beginning of the thread.

Message-ID: <1992Apr26.115609.18682@vlsi.louisville.edu>
Source record: 44654

A friend just gave me a working 386sx sans a graphics card and monitor. I can get a card for about $50.00, but don't wish to invest much in the ms-dos machine. Is there a way to wire a connector that will let a PC monitor card drive my sc1224 (made by jvc in 1985-86)? Resolution is not an issue to me. I just want to get the machine up and running then use it to transfer 5 1/4" disks from my office to the 3 1/2" in my st.

Wiring diagrams, descriptions of graphic modes and such would all be helpful. Baring the ability to use the sc1224, what multisync would work on both and how would it be wired.

Respond directly if you're concerened about net traffic.

robert royar r0mill01@ulkyvx.bitnet

1658. GNU C 2.1 and floats

Newsgroup: comp.sys.atari.st.tech

Does anyone know why I would get the following message when trying to link a program compiled with GCC 2.1?

blarf.o: Undefined symbol ___floatsisf referenced from text

As you may have guessed, 'blarf' is the only module in my program which uses float's. I am using the latest version (19) of mintlib and everything compiled just fine under GCC 1.40. Did I make a mistake in assuming that all I had to do was update my compiler binaries (.TTP files)? Or do I need another library?

Regards,

No, No, Not sure (probably another no).

Mega STe's do not have the Mega ST slot - they've got a VME slot instead.
Gadgets by Small say that they will be coming out with an SST for Mega STE's
and 520/1040 type machines but these SST's will be crippled because of space
problems.

You know, you're right. All those old programs of mine that open a VDI workstation in a TOS or TTP program are illegal in that they have a hardcoded '1' as a physical handle instead of using graf_handle(). I had forgotten about that. (Hey, this is code from 1987, when I didn't know any better!)

But, I still don't see why a TOS or TTP program can't do an appl_init(), graf_handle(), v_opnvwk() sequence. I have done it in a TOS program, so I know it works now. Someone mentioned that the appl_exit() would send an AC_CLOSE, but I can't see how that would be a problem either. If you were started from the desktop as a TOS/TTP, there's no way the DAs should have any open windows to worry about. If you were started from within another program, that program should have done an appl_exit() before starting you. (If it fails to do that, all sorts of ugly problems happen, because you end up with the same ap_id as the program that started you. I have a writeup on this bu{/issue somewhere, if anyone's interested.)

Well, you could write to ISD to see if a better DJ500 driver is out. Or you could try FPPRNT.PRG (auto program). This program speeds up output from PageStream, so it might work for Calamus SL.

> what does MiNT do to the TOS country number in the OS system header?

MiNT *shouldn't* be doing anything to the OS system header at all.
I just double checked the only code in MiNT that even references the system
header (at start-up, to determine the TOS version) and it seems to be
OK -- no '=' instead of '==' mistakes seem to be present :-).

My guess is that perhaps the method you use to find the OS system
header doesn't work under MiNT. What method *are* you using? Older
versions of MiNT (<0.93) didn't correctly return values from
the Supexec call; could this be what's causing your problem?

>Can anyone tell me how i unpack the .msa files on atari.archive?
You'll need either the Magic Shadow Archiver (MSA) or the Chaos Disk
Compactor (CDC). One or both should be up on atari.archive.umich.edu
under the names MSA_xxx or CDC_xxx. (Don't know the version or the
compression types...)
>Thanx in advance..
No problemo.

>blarf.o: Undefined symbol ___floatsisf referenced from text

gcc 2.1 is using new stuff in libraries. One of reasons is that
is supports new types, like 'long long', which did not exist before.
Therefore one needs libraries patchlevel 79 which were placed on
a.a. It is advisable to get immediately an update20.zoo and
raise patchlevel to 80. This is imperative if you are going to
hack and recompile libraries. If you will not do that expect
surprises.

It is somewhat unfortunate that we have now separate sets of
libraries for MiNT and for TOS. I hope that they will merge in
not so distant future. They are not so different. MiNT librararies
are based on older versions of gnulib which had known bugs.
This does not mean that the current gnulib is bug free, but that the bugs
are less known. :-) I did not trace MiNT libraries carefuly
enough to know the state in which they are right now.

BTW - the symbol in question provides an entry point to
long integer to single float conversion routine. Something
like that should be in MiNT library, I suppose. So with little
creative hacking you should be able to compile your program
even with old libraries.

1668. MGR

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-27 08:24:57 UTC
From: onstott@a.cs.okstate.edu
Message-ID: <1992Apr27.082457.22577@a.cs.okstate.edu>
Source record: 44665

Ok, I spent the last month getting all of the files relevant to the
MGR system. I have an Atari 1040ste, 4 megs ram, etc, etc. I have MiNT,
a bunch of utilities and the atarimgr.zoo and mgr.zoo files. I have
extracted everything, set everything up. Got all the environment variables
in place, a trick in itself, and have mintshel boot mgr automatically.

Result--> mgr loads, lets me open screens(finally no more "can't get pty"
messages), and I can play...for a few minutes. mgr consistantly locks
up. Especially if I am messing around with any of the more graphically
oriented programs from mgrdemos.zoo.

Is this a problem with mgr?(Ie, is MGR THAT unstable)?
Is there something in my configuration that could possibly be wrong?
Is this an indication that there is something wrong with my STe
Can mgr and/or MiNT run properly on an STe?

I have tried deactivating turbost (and all accessories for that matter),
deactivating blitter, bypassing Mintshel and going straight to MGR from
the mint.cnf file. As it stands, blitter is off, no accessories, no autoboots
(except the one that gets the time from my hard drive :-)). MiNT is loaded
from Superboot v.6.0. Using monochrome. Can't think of anything
else terribly relevant.(yeah right, it's ALL relevant buddy) Nothing I
do seems to affect mgr in any way, if it's gonna crash, it will crash.
Ocassionally I get PANIC errors(but they are to fast to see what they say)--
but that is only when mgr is being NICE. The most frequent error I get
when the stuff goes down, if I get a notification at all, is an error
reported by assert usually not being able to pull processes from the queue.

Has anyone had this sort of problem? I hope it is fixable as I really
like what I see of mgr--thought I might write some useful applications
for it.

Any help would be appreciated.

Exactly! They *all* have the same serial no. as seen from the ST side
of things. That's why *you* all should wait for my super disk
renumber program, coming to you *really soon now*, once I've gotten it
a bit more robust.

Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have a 520 ST from October '85. One of the first. So early that when I had the memory upgraded to a meg last year, they had to swap the mother board out because it was a "B" and they needed a "C" to do the upgrade. They got it done and it works fine. Now I am interested in a couple of new things. I want to upgrade from TOS1.4 to TOS2.06, to 2 meg of memory and maybe one of the new desktops, like NeoDesk. I have a bunch of questions that I am hoping the net can answer.

1. What does TOS 2.06 get me? What does it do or have that I don't have currently?.

2. What are the recommendations for desktop applications?

All help and replies are appreciated. Thank you in advance.

> So I guess some extended argument passing scheme must be used, such as
> ARGV or XARG. Is there a more intelligent startup for Sozobon?

Hmmmm... The startup code is part of the library, and Sozobon 2.0 doesn't
come with a library. It simply directs you to use dLibs. So if you're
using dLibs from the Heat and Serve package, you're going to get Heat and
Serve behavior; if you use the original dLibs 1.2, you're going to get the
argv[0] filled in by resorting to some black magic that has the child
poking around in the parent's memory space.

> So I guess some extended argument passing scheme must be used, such as
> ARGV or XARG. Is there a more intelligent startup for Sozobon?

All versions of dLibs use XARG if the information is available. Keep in
mind that dLibs was primarily written by Dale Schumacher, and XARG was
cooked up by Dale, David Parsons (orc) and some other folks.

As for a more intelligent startup module -- it depends on your point of
view, I guess, but the MiNT library supports ARGV and a Sozobon-compatible
version is available at atari.archive.umich.edu. Also, Ian Lepore has the
ARGV standard and may be able to get it integrated into the Heat and Serve
library by the next release.

Or you can roll your own. It's fairly easy to adapt the example code from Atari's ARGV documentation, but you'll notice right away that there are some fundamental problems scattered inside dLibs that need to be straightened out.

As I recall, the whole environment-handling mechanism needs to be fixed. The dLibs startup code passes an environment pointer as a third argument to main(). But instead of passing a char ** (as under Unix and MiNT), it passes a nonstandard char *. This is the same as a global environment variable that is referenced by getenv, putenv, and all of the process-control functions inside dLibs. If you're going to fix the environment pointer, you'll need to fix the functions that refer to it.

As I mentioned, you can always use the MiNT library instead. But there are some problems there, too. For one thing, its startup code drags in all sorts of library code that may never be needed in the program, making a minimum executable somewhere around 12K -- significantly larger than a similar program linked with dLibs. For another, the MiNT library really is not well suited to a 16-bit compiler. There are no long-allocation functions, so you can't grab > 64K of memory. Similarly, you can't read() or write() huge chunks of data, because size_t is a 16-bit value. (These limitations disappear when you compile the MiNT library with a 32-bit compiler.)

1675. Help in programming for MiNT

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-27 16:05:00 UTC
From: MORGADO@VXDESY.DESY.DE
Message-ID: <01GJCL97MKU89OD9WP@vax58b.desy.de>
Source record: 44672

I'm trying to write a couple of utilities for use under MiNT, using Lattice C5. For example I wrote the small prog below compiled and linked it to produce test.ttp. Then using bcgacc.acc I started up TOM_shell (small UNIX like command shell) and ran test.ttp from it. All is fine... However if I go back into the GEM desktop and try to do `anything' I find that test.ttp is taking up so much `CPU time' that to open a folder I have to double click on an icon more than 20 times (on average) before anything happens. Then I get the buzy bee and I have to wait another 10 secs before the window is opened and drawn.

```
#include <stdio.h>
int main(void)
{
int i
for (i=1; i=1000000; i++;)
{ printf("Hello world\n"); }
}
```

I'm aware that I can lower the priority of a process using MiNT and hence (although I haven't tried it) probably solve my problem that way. However the problem puzzles me, and I think it arises due to something I'm doing, or not doing! I have run many other .ttp and .tos programs (not written by me, and not written to run under MiNT either) in the background without this problem. Hence it must be something I am doing wrong!

Can anyone out there help? I must add that I am very new at programming the ST and am in the process of learning C, so please excuse me if this is a really trivial problem. I would nonetheless be very grateful for any help.

Many thanks in advance, Carlos

Too bad... well, I'm not trying to check for the presence of a specific
gdos but want to print the numer (and name, if possible) of the installed
gdos. It's for a shell command that prints all kinds of version numbers,
like TOS, GEMDOS, MiNT, and gdos.

Hi

If I try to run the tcsh (Mint version) 6.00.03 or like that
within MW (in one window) tcsh just says BUSERROR and exits.
If I start the Shell from the desktop everything works fine :-)
What has to be done to scripts or ?? to make it run nicely beneath
MW. is it a problems with MW's Pseudottys which get created and tcsh don't
likes them ? Could someone tell me more.

Thanks,
Wolfgang

It's the old problem with accessing os_conf. It was discussed ~ 4 weeks
ago here or in comp.sys.atari.st.

The correct way to get the os_conf value is:

```
UWORD
get_conf (void)
{
LONG savessp = Super (0L);
OSHEADER *O = *((OSHEADER **)(0x4f2L));
Super ((void *) savessp);

O = O->os_beg; /* wegen eines Fehlers in einer alten
AHDI-Version */
return (O->os_conf) >> 1;
}
```

Trap #2 is set early enough (by the VDI, not the AES). You can do the
appl_init() call and test the AES version number to see whether the AES is
installed (if the version number in the global array remains zero, there's
no AES). This is perfectly legal and even is used by MACCEL3.PRG.

```

This may or may not be connected to your problem - how did you fetch "syshdr"?

The proper way is:

```
SYSHDR *syshdr, **sysbase = (SYSHDR**)0x4f2 ;
syshdr = (*sysbase)->os_base ; /* offset 8 */
```

For some reason unknown to me, TOS versions newer than 1.02 copy part the ROM sysheader into RAM during the autoboot phase.

Depending on your harddisk driver, the RAM sysheader may still be active during execution of the AUTO folder. If MinT is run from the AUTO folder, the sysbase pointer may never be reset to the ROM copy...

If you happen to use

```
syshdr = *sysbase ;
```

to fetch the pointer, you'll get a pointer to the RAM copy.
As far as I know, the "palmode" field is not valid in this copy, which could explain your problem...

The other method ((*sysbase)->os_base) should always work correctly!

1682. Getting GCC/G++ 2.1 to work (without pragma warnings)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-28 04:59:39 UTC
From: dmb@wam.umd.edu
Message-ID: <1992Apr28.045939.18069@wam.umd.edu>
Source record: 44679
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I've finally gotten hello.c and hello.cc to compile without warnings.
Here are some hints for getting things to work. Many of them have
already been mentioned, but I thought I'd post a summary since some
people are still having trouble.

How to make GCC/G++ 2.1 work:

1. Get more memory. 4 megs may not be mandatory, but I
haven't yet read of anyone successfully compiling anything
with less. The binaries are now up around the 1 meg range,
and it's only going to get worse, so why not upgrade now
while DRAMs are $4 and SIMMs are similarly cheap. G++ seems
to work comfortably with 3,000,000 bytes free, so you
could have MiNT and a nice shell running. (I haven't tried
2.1 under MiNT yet. I assume it works.)

2. Make sure all the pieces are there. Run GCC with the -v
option to see what it's doing. My setup didn't work for
a while because I forgot to copy gcc-as.ttp from my 1.41
directory into my new 2.1 directory. The error messages you
get aren't very informative ("cmd exit code -1" from Gulam)
so you need to check the verbose output of each stage of the
compilation process.

3. Make sure your make.ttp knows how to pass arguments under
the argument passing scheme your shell uses. I'm using
the Sozobon make, which won't work if you have "set
env_style mw" in your startup .g file. If GCC reports
"no input file specified" this is a clue that your
args aren't getting through.

4. Change "once" to "idempotent" in all the files in your
include+ directory to make G++ stop complaining about
obsolete pragmas. I've already done this; if there's
demand I can upload the modified directory to atari.archive.
(If #pragma idempotent is not appropriate here, someone
let me know. I believe it's the "non-obsolete" term.)

Hope this helps. Everything you need for the wonderful GCC/G++ 2.1
combo is on atari.archive; you just have to put all the pieces
together. A thousand thanks to everyone's who's made 2.1 possible on
the ST.

Happy hacking!

Dave Baggett

> sozobon argv[0] is empty ("")

Yep. As far as I know, Atari has never provided a legal documented way to get the actual path/name of the program at runtime, so the sozobon startup just plugs in an empty string.

> is there a more intelligent startup available

Yep. It's called HSC v1.34, coming soon to a PD outlet near you. In the past couple days, I've added full support for ARGV and xArg parm passing, both on received parms and when starting other program via fork()/spawn(). I've been testing it all day, and the new startup seems to be working fine, so now I just have to relink the compiler and tools with the new libraries.

> I don't know what Ian has done to the startup since I don't have
> sources.

Yeah, well, don't feel bad, neither do I. ::grin:: I have something that claims to be the source for dlibs v1.2, but I keep finding subtle differences between the source and the existing object code. As I find them I fix them; someday I'll have complete sources, if I don't just punt dlibs and start distributing mint libs instead.

1684. Re: What does MiNT do to TOS count

>the ROM sysheader into RAM during the autoboot phase.

That's because of a bug in a very old AHDI version where the TOS creation date was searched in a wrong place. If the BIOS would't do that copy, this AHDI-Version would overwrite some (wrong!) local variables of GEMDOS, that's why Atari did this 'hack' (at least I think so).

This whole thing is documented in the Rainbow TOS Release Notes, in our book 'Atari Profibuch ST-STE-TT' and was discussed here some weeks ago (where Ken Badertscher explained it again).

1685. How to redraw whole desktop?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-28 12:56:29 UTC
From: tony@microware.co.uk
Message-ID: <948@mwuk.UUCP>
Source record: 44682

I wonder if someone can help with a GEM programming question?

I am writing a GEM-based program which uses the default desktop grey/green background, and installs a menu bar.

One of the things the program wants to do is to go into alpha mode to do some terminal emulation or to execute the shell() function from dLibs.

I can do that OK as follows:

```
v_hide_c(vhandle);
v_enter_cur(vhandle);
v_clrwk(vhandle);
v_curhome(vhandle);
```

The problem is, when I exit from this mode, how do I get GEM to restore the original menu and desktop background? If I just use:

```
v_clrwk(vhandle); /* probably not necessary? */
v_exit_cur(vhandle);
v_show_c(vhandle);
```

then the desktop doesn't get redrawn. I have even tried opening an additional virtual workstation, and closing it afterwards, but that made no difference.

I think I have the above code fragments correct - the details are at home.

What should I be doing?

Tony.

1686. SCSI info wanted for TT

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-28 13:45:30 UTC
From: leo@ahx.hobby.nl
Message-ID: <1302@ahx.hobby.nl>
Source record: 44683

Hello,

I already posted this article to comp.sys.atari.st a week ago but I got nearly no response. Maybe I get more luck here!

I like to play with the SCSI interface present on my atari TT. I have found a Minix driver for SCSI written by Bruce Culberstson that was using the same chip as present on my TT (NCR5380). But when I try for instance to reset the SCSI bus as described in that source code the controller seems to go nuts.

To access the chip, I use the odd addresses starting at FF8780. The code to reset the bus looks like:

```
reset_bus()
{
int i;
unsigned char *chip = (unsigned char*)0xFF8780;

chip[5] = 0;
chip[1] = 0;
chip[3] = 0x80|0x40; /* assert RST?? */
for(i = 0; i < 100; i++);
chip[3] = 0x40;
chip[15] = 0x6|0x80;
chip[15] = ~(0x8|0x4);
for(i = 0; i < 5000000; i++);
}
```

After this code has run, all registers on the chip seem to contain 0xff????

If there is anyone who has any info on the TT SCSI-bus or on the NCR5380 please respond. I am also interested in other one's code to access this bus.

My email address is: leo@ahwau.ahold.nl

Thanks in advance,
Leo Weppelman.

1687. GCC/G++ 2.1 HELP???

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-28 14:35:44 UTC
From: malay@sae.com
Message-ID: <1992Apr28.143544.7298@sae.com>
Source record: 44684

I need some help!!! Here are the files that I downloaded and their contents

gcc21bin.zoo
libolb79.zoo
gmlibo22.zoo
pmlolb17.zoo
utlbin25.zoo
includ79.zoo

Is this all that I need to get GCC/G++ 2.1 to work? What environment vars
(if any) that are different from previous versions of gcc/g++ need to be
set?? Also, if you have GCC/G++ 2.1 does :

gcc hello.cc -o hello.ttp -lg++

actually work??? My version of "gcc.ttp" keeps attempting a call to
"cc1plus" (even though GCCEXEC is set to c:\bin\gcc-). It seems to me
it ought to be calling "c:\bin\gcc-cc1+.ttp". If I do :

gcc hello.c -o hello.ttp

everything works fine and dandy. So either my environment is missing
something or "gcc.ttp" has a bug in it????

Here's what I have:

```

> }
```

That is interesting. First this program should not compile (missing ; after 'int i'). Even after this would be fixed it should return immediately since loop condition would not be satisfied (1 != 1000000). And third main() is missing return value, which means that it returns some garbage to its caller. Should make a lot of shells happy :-). You are not telling the whole story.

Hey all... to drop back to the subject of .MOD files for a moment here,
I'm trying to find a way to get a queue of files to play in the background.
I just found a program to play .MODs in the background on a normal ST (and STE
of course), and I thought that was a big step. :) So, if anyone has info on
how I could get a collection of .MODs to play, it would be most helpful.

Thanks..

1690. STalker lockups & Phantom Typist

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-28 18:01:04 UTC
From: atilghma@sdcc13.ucsd.edu
Message-ID: <32161@sdcc12.ucsd.edu>
Source record: 44687

I have two problems to throw against the collective net.wisdom:

1) I have STalker 3.01 installed as a DA. If I invoke it via the "Desk" menu *before* having run a normal PRG/TTP/etc., the system tends to lock up when a new GEM window is opened [it happens when I open other ACC's, or when STalker tries to put up its "file transfer status" window]. If I run any program *before* doing this, the problem goes away. This didn't happen before I installed TOS 2.06. It also doesn't care whether MiNT is loaded or not.

2) The "phantom typist" has suddenly started haunting me with a vengeance -- four times in the last week, and before that, maybe twenty times is the past FIVE YEARS. I haven't added anything to my system lately except MiNT 0.94 vs. 0.93. Any ideas?

Any suggestions?

This sounds like a known problem in Eric's original tcsh port. It would
bomb when run from pseudo-ttys. You should try to get the very latest
version of tcsh from atari.archive.umich.edu. I haven't tested it, but
it is supposed to fix the problem (actually a problem in the MiNT libraries
it was compiled with).

There is a workaround for the old tcsh: add symbolic links to your
mint.cnf script which link MW's pseudo-tty pipes (in u:\pipe) to
entries in the u:\dev directory.

Actually, the expression i=1000000 just sets i equal to 1000000
on each loop. The construct should loop forever as there is no
testing condition. Finally the ; after i++ is probably bogus too.

i>from within another program, that program should have done an appl_exit()
i>before starting you. (If it fails to do that, all sorts of ugly problems

Not true! At least the old desktop leaves the Windows open when starting a
TOS propgrm. So does for example Gemini, when it starts such a program in
it's console window.

If you do such things under MiNT and existing AES, it's even worse,
because the program may run in the background screwing everything up.

>testing condition. Finally the ; after i++ is probably bogus too.

OK, the person who answered the question posted buggy code, but no one really answered his question. Let's assume what he wanted to say was something like this:

```
#include <stdio.h>

int
main()
{
while (1) {
printf("I'm still here...\n");
}
}
```

One cause for this slowing things down so much is that it's a very tight loop doing lots of I/O. It might help if you changed the loop so that each time through the loop you tell MiNT "OK, you can have some time for other processes now." The way to do this looks like this:

```
#include <stdio.h>
#include <mintbind.h>

int
main()
{
while (1) {
printf("I'm still here...\n");
Syield();
}
}
```

Note that this requires the mintbind.h file, which comes with GCC but not lcc (which the person with the question is using.) I'm not sure if there's a mintbind.h for lattice, but the GCC one should at least give the bios function number used by MiNT for Syield(), so you could do something like "bios(0xNN)" where NN is the number of the routine for Syield(). (Come to think of it, it might even be a Gemdos level function... don't have my docs handy)

Cheers,

Before I get flooded with letters with corrections. Yes, I know
(really, honest, sigh...) that 'i=1000000' is an assignment and
not a test and that the loop - once compiled - executes forever.
Once again this shows that I should not respond on-line and fast.
Sigh again...

> ntomczak@vm.ucs.ualberta.ca

Actually, it will loop for ever because i=1000000 will be non zero (you are
assigning 1000000 to i, and the whole expression evaluates to 1000000). If you
had put i==1000000 it would terminate immediately. What you probably meant to
say was i<=1000000 (typing error possibly?). The usual C convention for
repeating something n times is
for (i=0; i<n; i++)
statements;
A better (faster, shorter) method is this:
for (i=n; i--;)
statements;
This way you are comparing with zero instead of a number each time around.
In addition you have a semicolon after the i++ in the for statement. I don't
know whether this is legal C, but it is certainly not needed.
The curly brackets are also not needed (Although I accept that they may be
left over from when you had something else in the loop.
The "printf" can be replaced with "puts(char *str)" which has exactly the same
effect (except that it automatically puts a newline on the end), but saves
having to include the code for printf the the executable (Several Kb)
Sorry about being a smart-arse, especially as this has nothing whatsoever
to do with the original question, but I couldn't resist it!
```

> v_show_c(vhandle);
>
>then the desktop doesn't get redrawn. I have even tried opening an
>additional virtual workstation, and closing it afterwards, but that made
>no difference.

What you need to do is:

```
v_exit_c(vhandle);
form_dial(FMD_UPDATE, x, y, w, h);
menu_bar(menu, ON);
v_show_c(vhanle);
```

Also add:

```
menu_bar(menu, OFF);
```

to your "enter alpha mode" code to be on the safe side.

If you are not using the VDI for anything else, I would be tempted to avoid it
by doing:

```
graf_mouse(NULL, M_OFF);
menu_bar(menu, OFF);
```

```
Cconws("\033E");
```

and then

```
form_dial(FMD_UPDATE, x,y,w,h);
menu_bar(menu, ON);
graf_mouse(NULL, M_ON);
```

Where x,y,w,h is the work size of the desktop. I think they are returned
by graf_handle(), but if not use wind_get(WF_WORKSIZE, whand, &x,&y,&w,&h)
where whand is zero (The desktop itself).
There is a 100% chance that some of these arguments are in the wrong order, or
what the constants are spelt differently - Look the functions up to check.

If you have a desk accessory that wants to do this you have a problem because
you don't know the address of the menu tree to restore the menu bar
afterwards. The only solution is to blit the menubar part of the screen (I'm
not sure where you would get the height of the menubar from) to somewhere
safe, and then back again afterwards (or intercept menu_bar calls to get
the address).

I any case, the alternative is to blit the whole screen somewhere safe and
then blit it back again. However this is not a good idea because you might
have insufficent memory (especially on large screen monitors etc.)

You force GEM to redraw the desktop by "pretending" you've had a dialogue box that was the size of the desktop. Use a form_dial(FMD_FINISH,...) call with the coordinates, width and height of the desktop -- this sends a redraw message to all applications, including the AES screen manager, and AES will re-draw the desktop.

You can get the coordinates etc of the desktop by asking for the coordinates etc. of the workspace of window zero. Note that only the desktop will be restored -- you'll have to either save the menu bar image somewhere, or re-install your menu bar.

1700. TT's ST-ram

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-29 16:32:19 UTC
From: alien@clinet.fi
Message-ID: <1992Apr29.163219.28563@clinet.fi>
Source record: 44597

I'm plannig to get some new memory to my TT. It has now only 4 megs ST-ram, there's not any of TT-ram, not even this TTramcard, wich I would need if I wanted to get some TTram. However, I'm runnig out of memory and I found one cheap and fast way to get some more.

Because I'm using graphical applications, which uses ram for storing animation and pictures, I've no need for expensive TTram, ST-ram can do things enough fast. More important to me is the size of memory, speed will come after that.

So, I opened TT to find out, is there any way to get more ST-ram. Fist, under the hardisk was one ST-ram-card, and under that 8on motherboard) were more ST-ram- I removed this st-ram-card to find out how much memory it was holding, and after boot tehre was only 2 megs ram instead of 4. So, after fast count, I noticed, that on TT's motherboard were 2 megs of ST-ram in 16 chips. So, replacing these 16 4C4256-10 chips with 512 or 1024 chips would increace ST-ram up to 6 or 8 megs depending what odel of chips I would use. But before I do anything, I want to find out, is this kind of memory upgrading possible? Has TT any ST-ram limit and if does, how much is the max. size of St-ram? 8 or 16 megs? Less? More? (usefull utilities)... What's the point of having extra ram-card if there's enough room (on motherboard) for more ram?

So, if you know anything of upgrading TT's ST-ram, please mail me and tell what you know.

1701. Using a Sony MultiScan monitor

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-29 18:02:38 UTC
From: coutu@decvax.dec.com
Message-ID: <1992Apr29.180238.12481@decvax.dec.com>
Source record: 44598

By now I can clearly see that NEC MultiSync monitors are well supported by various vendors who provide the necessary adapter hardware to make them work correctly.

I have the opportunity to obtain a Sony MultiScan monitor and want to know if the hardware necessary to use it exists someplace. I've verified that the specs of the monitor will satisfy the ST's requirements but really don't want to have to play with making my own cable and speaker assembly.

Does anyone know if I can use this thing?

Setting argv[0] to "" is the correct (or at least, ANSI mandated) thing
to do if the program's name cannot be determined. This will be the
case if either (1) the library doesn't support some extended argument
passing scheme, or (2) the shell calling the program doesn't support the
same scheme as the library.

[About the MiNT library]

> limitations disappear when you compile the MiNT library with a 32-bit
> compiler.)

size_t should always be 32 bits on the ST, unless your compiler doesn't
support objects >64K in length (in which case there's not much point in
malloc'ing such objects). Sozobon is broken in this regard. gcc can use
16 bit integers, and mntlib works fine with them.

As for read() and write(), mntlib provides functions _read() and _write()
that take long parameters. If you like, you can #define lread _read
and #define lwrite _write; this isn't the default, because the identifiers
"lread" and "lwrite" are in the user's space, not the library's (and
I have in fact seen programs that use these identifiers: Larn is one).

Connecting a MultiSync monitor to the Atari ST...

We have a text file in listings here on Bix, MULTISY.TXT, that describes hooking up an older NEC Multisync 2D type monitor to an ST. The newer multisync monitors (NEC 3D/4D/5D and equivelents) are becoming more popular, and they have a different type of connector than the older 2D models, so this is an updated description of how to build a cable for these newer monitors. This description will also be posted in listings as MULTISY3.TXT.

This document describes my experiences with a 1040STFM. If there's a difference for a MegaST, I'm not aware of it (someone please let me know).

THINGS YOU WILL NEED:

- A cable with an ST-type 13-pin DIN connector at one end, and a bunch of bare wires at the other. Practical Solutions makes just such a cable, it retails for about $20 hereabouts.

- A 'High Density 15-pin Female D-Sub' connector. Also known as a High Density DB15. Radio Shack 276-1419 or equiv. $5 or less.

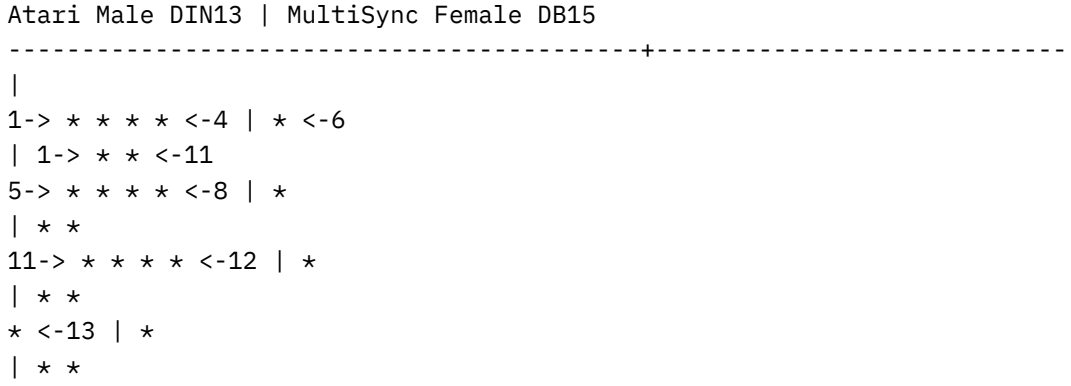
- A metal hood for the DB15, unless you're going to make a switchbox and mount the connector in it. Radio Shack 276-1508 or equiv. $2.

- A pair of needlenose pliers and a little screwdriver.

- A big cup of coffee. (The jitters will add an exciting element of challenge when you try to work with them little crimp connectors on the DB15).

THE CONNECTORS

Now, some pictures of what the connectors look like. Both of these are pictured from the front, that is, you're looking at them from the side opposite of where the wires go in:



```
| * <-10
| 5-> * * <-15
|
-----------------------------------------+---------------------------
|
1 - Audio out YLW/WHT | 1 - Red in
2 - Composite video CLEAR | 2 - Green in
3 - General Purpose Output | 3 - Blue in
4 - Monochrome monitor detect YELLOW | 4 - N/A
5 - Audio in | 5 - N/A
6 - Green output GREEN | 6 - Red ground/return
7 - Red output RED | 7 - Green ground/return
8 - 12 volt pullup BLACK | 8 - Blue ground/return
9 - Horizontal Sync BROWN | 9 - N/A
10 - Blue output BLUE | 10 - Ground
11 - Monochrome output ORANGE | 11 - N/A
12 - Vertical Sync WHITE | 12 - N/A
13 - Ground COPPER | 13 - Horizontal sync
| 14 - Vertical sync
| 15 - N/A
|
RGB signals 1v pp 75 ohm impedance | Pins marked N/A should not
Audio is 1v pp 1k ohm impedance | be attached to anything when
H/Vsync are TTL, neg, 3.3k ohm | building the cable.
The colors are for my Practical Solutions |
cable, yours may differ! |
-------------------------------------------------------------------------
```

THE CONNECTIONS

Okay, now for the connections. At this point you have to make a decision: are you building a cable for a monochrome monitor, one for a color monitor, or a switch box that handles both? Building a switchbox is a more complex project (I haven't tried it); I'll expound on that later. Otherwise a cable is going to work for color or monochrome, but not both.

To make the cables, connect the pins as follows:

```
COLOR MONOCHROME
DB15 ST DB15 ST
---- -- ---- --
1 7 1 11
2 6 2 11
3 10 3 11
6 13 6 13
7 13 7 13
8 13 8 13
10 13 10 13
13 9 13 9
14 12 14 12
4->13
```

You'll notice that some wires from the ST aren't used. Just trim them neatly so that no wires stick out past the insulation to cause shorts. Also note that in the monochrome configuration, ST pin 4 is tied to ST pin 13 (ground). This is what informs the ST that a monochrome monitor is attached. The other difference in the monochrome cable is that the single monochrome output line attaches to all 3 RGB input lines on the monitor.

You may also have noticed that MultiSync monitors don't have builtin speakers. You can handle this (if you care) by attaching a standard RCA audio plug to ST pin 1, and having it come out the side of the cable near the DB15 plug. Then you can plug your ST sound into any audio amplifier. (I recommend that you ransack your little brother's or sister's room or dig around in your closet, and look for one of those old $89 stereos that everyone had as a kid. You know, the one that has an 8-track player and a turntable that eats records. You can generally strip one of those down to a nice compact audio amp that mounts in a little (say 8x6") box. Connect up an old half-dead car speaker, and you have an outboard sound system that performs at least as well as the builtin speaker on an ST monitor).

CONSTRUCTION TIPS

Okay, so you've read through the instructions a couple times, you've finished that big cup of coffee, and the caffeine buzz is in full swing. It's time to assemble the DB15 connector. If you've gotten the (overpriced) Radio Shack part, or a similar crimp-style connector, you're going to find the assembly to be tedious. Take your time, because you have to get it right the first time on each pin.

Strip the wire very carefully to expose exactly the right amount to fit in the crimp slot. If you stripped too much, trim it; you don't want bare wire extending past the end of the crimp connector when it's inserted into the plug housing. Conversely, you don't want any of the insulation to get caught in the crimp, because then the connector will be too fat to insert into the plug housing all the way. After you have the bare wire trimmed to the right length, twist it a little bit to keep it from fraying, lay it in the crimp trough, and with a needlenose, carefully crimp down first one side, then the other, on the little crimp flaps. After getting the crimp into a basically rounded shape, go back over the flaps and crimp them down a bit more. But be carefull, you don't want to mush them flat or they won't fit into the plug housing. When you think you have it right, and the crimp is nice and round, but snug, tug on the wires a bit. If they come lose, or even wiggle a bit, fix it now. Once you have the connector inserted in the plug housing, it will never come out again. If you get it inserted, and then a wire pulls out leaving the connector behind, you lose. Go back to Radio Shack, slap down another $5, and you're ready to try again. (Given my famous lack of manual dexterity, I'm proud to say that I only ruined one connector before I got it right.)

If you are good with a soldering iron, it can be helpful to put a VERY SMALL amount of solder on the crimp connector after the wire is crimped in. Use a small cool iron, and very fine solder (eg, .035 diameter). If you put too much solder on the connector, it won't fit into the plug. If you try to force it in, it'll bend. If you use too much heat, the

insulation will retreat up the wire, and after you get all the connectors inserted, they'll make a neat little spark show. (They don't call them high density connectors for nothing!)

On the DB15 connector, four of the wires attach to the ground wires on the ST cable. Since the ground connections are all in a row on the DB15, you can avoid a rat's nest of ground wires by making a set of pin-to-pin loops on the DB15. In the middle row (pins 6-11) of the DB15, make connections as follows:

```
6-> ** ** ** ** ** ** <-11
| || || ||
| || || ||
\---/\---/\--------/|
| <- to pin 13 of ST cable.
```

Be sure to use fairly fine wire to make these loops, you won't have room to lay two fat wires next to each other in the crimp trough of the connector. (Bell wire is too heavy, for example). If you're making a monochrome cable, you can use this same technique for the RGB connections (DB15 pins 1-2-3). When making these loops, assemble all the connections first, then insert all four connectors at once.

If you're paranoid, like I am, you can strengthen the wires after you've got the DB15 all assembled. Mix up a little batch of 5-minute epoxy (don't use the 24-hour kind), and let it set for about 90-120 seconds after you've mixed it, so it's begining to get stiff. Using a toothpick, goop the epoxy all around the wires where they go into the back of the DB15, but don't let the epoxy get down into the holes. After you've got the epoxy smeared all around the bases of the wires where they enter the plug housing, suspend the plug upside down (so the glue can't run into the holes) for 10 minutes or so until it hardens. This step can be especially handy if, despite your best efforts, some bare wire (other than the ground wire, which is always bare) ends up showing after all the connectors are inserted. Epoxy makes a fine insulator, and this will ensure that wiggling the cable in the future won't cause shorts.

Once all the connections are made, use a metal connector hood, and ensure that the ground (ST pin 13) is connected to it, for shielding.

HOW ABOUT THAT SWITCHBOX?

All of the above I have tested and I know it works. The following is untested, and I'm not even sure the appropriate parts are available. The idea here is that you have a little switchbox with a cable going to your ST, a cable going to your monitor, and a switch that lets you choose color or monochrome operation. The switch is the only tricky part, you need a four-pole double-throw switch. I'm thinking a rotary 'ganged' switch would do the trick, if such are still available. The connections would be as follows:

DB15 SWITCH ST

```
o--------- 7
1 ---------o---
o--------- 11

o--------- 6
2 ---------o---
o--------- 11

o--------- 10
3 ---------o---
o--------- 11

+---------------- 4
|
| o--------- N/A
+-o---
o--------- 13

6,7,8,10 ---------------------- 13 (These are straight-thru, not
13 ---------------------- 9 thru the switch).
14 ---------------------- 12
```

With this setup, use a small *metal* hobbyist box (available at Radio Shack), and mount the DB15 and the ST cable thru the back of the box, and the switch in front. Connect the ground (ST pin 13) to the box for shielding purposes. Also, remember that when you switch monitor types, your ST will reboot itself!

WRAPUP and DISCLAIMER

Well, that's it. It took about 2 hours to make a cable (counting the first failed attempt with the nasty crimp connectors). Someone with more manual dexterity than I have should be able to do it in half that. While I have successfully followed these procedures myself, I cannot, of course, take any responsibility for problems that may occur with your system, or damages that may result from your using these procedures, including problems caused by inaccuracies that may be found in this document. I always hate saying things like that, but gotta CYA, you know? I can't afford to buy the world new monitors because of typo.

I'm having some problems loading my own external fonts. I have created numerous fonts from the FED utility,a font editor from Degas Elite, and some other pd font editors. The problem is that when I try to install them using pre-defined functions in Laser C, my program always bombs.

My question is this: Is there a way to just incorporate the font code into my program and poke the system font vector to point to my font? If so what are the vectors for low and medium resolution fonts? I have the sys vector for the hi res font.

Also where can I get a font editor/converter to convert hi rez fonts to low and med res fonts?

On the subject of mgr, can someone post the fix to get mgr and tcsh to coexist happily. I seem to remember its simply a case of making a link, but I can't remember the details.

Note, I'm not talking about the 'can't get ptty' error, I'm talking about the bus error I get when tcsh tries to run in a window under mgr.

My PC at work has a "show" command in its ftp programme, but that
doesn't seem to be a standard feature. On a VAX you can just say
"get file TT:" -- I guess on a PC you should be able to do "get file con:".

It's certainly true (at least in my experience) that you can't compile
large files without 4 megs. I had trouble getting GCC 1.41 to compile
many of the Nethack files (which are up to 85K) on a *bare* ST; i.e.,
no AUTO's, no ACC's, using 20K Sozobon make.ttp instead of the
gnu_make.

Since the 2.1 binaries are even bigger than their 1.x counterparts, I'd
suspect that potential problems are even worse.

However, I ran some informal tests and it seems that RAM use is heavily
dependent on the compliexity of what you're compiling. GCC 2.1 will
compile hello.c without optimization with only 1,000,864 bytes free
but fails when you get down below 1M. I don't know how optimization
affects memory usage, but if you're strapped for memory keep your
files very small and perhaps compile without -O.

Source record: 44613
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

Dear Netters,

I hope this isn't to much of a FAQ, but I am preparing to do a memory upgrade on my stock 1040STe. So I had a few questions:

#1. What is the maximum amount of ram I can expand to?

#2. Why do the simms I have in my STe have a (diode?) soldered across pins 1-16?

#3. Do I need to but special simms, or can II run down to Costco and buy 70ns 1 meg "generic" simms?

Any help would be greatly appreciated. Please reply via E-mail.

Thanks in advance,

> 16 bit integers, and mntlib works fine with them.

I've seen this statement applied to the Sozobon compiler a couple of times. Yet I regularly allocate more than 64K of memory using dLibs, read entire files into RAM, and process the data using pointers. It works. There may be a problem with statically allocated storage > 64K (not something I've ever done; I figure anything in that range is malloc territory ... you certainly can't declare an auto variable of that size). Anyway, the point is that it is useful to allocate >64K with Sozobon C, and that's why you see weird stuff like lalloc in dLibs.

I think the fundamental problem with size_t and Sozobon C is that there are library functions that traditionally have been documented as taking an unsigned and/or int argument, but under ANSI are documented as taking size_t. Consider fread:

```
int fread(ptr, element_size, count, stream)
char *ptr; /* void * under ANSI */
unsigned element_size; /* size_t under ANSI */
int count; /* size_t under ANSI */
FILE *stream;
```

If you typedef size_t as unsigned long, then feed fread(buf, 1, 32, fp) to a compiler with 16-bit ints, how is the compiler supposed to know that the arguments have to be promoted to 32-bit values? The answer with GCC is prototypes. But a Classic C compiler like Sozobon (and its offspring Heat and Serve C) doesn't do prototypes. This kind of a bug is a real booger to track down.

> As for read() and write(), mntlib provides functions _read() and _write()

> I have in fact seen programs that use these identifiers: Larn is one).

That's a useful bit of information to know. Thanks. It's good to remember that pre-ANSI libraries such as dLibs use identifiers that may clash with user programs. Some of them are attached to some very useful functions, such as wildcard(), but if somebody writes a card game program and uses a variable called wildcard there's liable to be trouble.

I guess the real solution to all of this is for Ian Lepore to quit working, eating, sleeping, and having any sort of a real life and get down to rewriting Heat and Serve C from top to bottom as an ANSI-conformant compiler with switchable support for both 16- and 32-bit ints. :-)

EVERYONE: PLEASE stop posting the same messages in both the ST.tech areas AND the regular ST area. It's a waste of space, and a waste of time wading through them. This message obviously belongs here, since it's technical in content, but I see lots of For Sale messages, and lots of others duplicated on the two newsgroups.

And now, back to your regularly scheduled message:

Your 1040STE can go to 4 meg max. You can use any 1 meg SIMM you can find, be they 1x8 or 1x9. It doesn't matter. You don't need to spend the money on 70 ns versions, as 120 ns will work just as well. The ST's MMU is designed to run at 150 ns, so faster SIMMs are pretty pointless.

The reason for the capacitor on some SIMMs are as filters. Not all SIMMs have them. For example, the ones in my Mega STE are completely surface-mount, and don't have those caps on the back. My old 256K SIMMs do have them.

If you're only installing two meg at a time, then they 1 meg SIMMs go in the second and fourth slots, looking at the machine from the front.

> do the job.

yes, this appears to be so. crt0.o and gcrt0.o from PL79 will
do just fine, or you can easily compile crt0.c as per the Makefile
(both 16 and 32 bit int use the same crt0.o)

> (2) On my machine (TT 030/8) I made J Bammis test suite (file test03s.zoo
> in /atari/gnustuff/tos/gnulib) with gcc 2.1 PL 2 and libs PL80.
> Approximatly 1/3 of them did _not_ work correctly. i.e. gave wrong
> output or bombed (one of them).

the one that bombed needs a large stack. fixstk -1 tbcopy.ttp
should do it. 1/3 of them should NOT have failed. please let me know
your exact diffs of failures. Note that on tstdio explainable errors
occurs (what is happening is that the test is doing input after output
without and intervening seek on a stream open for read and write. this
behavior is undefined).

> (3) In C++ mode :
> The compiler driver does _not_ atutomatically link the g++.olb
> object library (bug or feature ??).

this is correct: the correct way is to add -lg++.
gcc -o hello.ttp hello.cc -lg++
you can easily clone the g++ shell script in the gnu
distribution in your favorite shell script language. (note g++.ttp
does not exist any more)

> compiles, but the linker complaines about lacking symbols like
> ___main (!!) and _cout, although the g++ library was linked explicitely

huh? please try gcc .... -lg++ -v, to see whats going on. (note the -v)

>want to have to play with making my own cable and speaker assembly.
>
>Does anyone know if I can use this thing?

What's the model number of the Sony?

The type and amount :^) of hardware you need is contingent upon what the
pin-out is of the monitor's cable. The IB Computer's MultiSwitch has a
9-pin male (!!) plug at the end of a long cable. The Omnimon Peripherals
Omnix3 has a 15-pin female jack, although a 9-pin version is available.
Also available are adapters for the MultiSwitch if you need it. I used
an adapter with the MultiSwitch since there is a 15-pin male plug on
my NEC 3D's cable.

My recommendation is to go with the Omnix3 if you care to spend the money.
I think it's $79.95 direct from Omnimon Peripherals. The IB Computers
MultiSwitch is $50 or $60. Omnimon Peripherals: 714-753-9253. Tell them
I sent you. :^) And tell them what monitor you have. They'll be able to
help you.

>
>If you typedef size_t as unsigned long, then feed fread(buf, 1, 32, fp) to
^^^^^^^^^^^^^^^^^^^^

personally, i consider this rather poor programming practice. i think it is always better to at least try and cast constants to something "prototypical". before ANSI C, this was not always a good thing. however, what with POSIX.1 and ANSI, it would be better to get in the habit of doing:

```
fread(buf, (unsigned) 1, (int) 32, fp)
or (ANSI):
fread(buf, (size_t) 1, (size_t) 32, fp)
```

the latter is totally unambiguous in the ANSI domain, no matter what size_t turns out to be. at least the code compiles and (probably) runs. i am not sure what happens to things like (size_t)100000 when size_t is only 16 bits, however. today, it is necessary for size_t to be long. tomorrow, with >2GB file systems, long long may be needed.

ideally, even if sozobon is not ANSI, its libraries (and headers) should be. at least we should get in the habit of using standards since they exist for some very good reasons (other than generating lots of compiler warning/error messages). at least you know the interfaces are correct. at this point, i'd call a non-ANSI compiler and non-POSIX libraries "broken", especially if code is to be reused on other (non-ST) platforms. this is just one of the reasons GCC is such a good "investment" (it linting capability).

1723. MiNT question: Pgetpid buggy?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-04-30 18:14:34 UTC
From: wr@bara.oche.de
Message-ID: <H.y7T15sR1XFQ@bara.oche.de>
Source record: 44619

Hi all,

it seems that the MiNT system calls Pgetpid and Pgetppid don't work the
way they ought to... the following program:

```
#include <stdio.h>
#include <mintbind.h>
main()
{
printf("pid = %d\nppid = %d\npgrp = %d\n",
Pgetpid(),Pgetppid(),Pgetpgrp());
return 0;
}
```

produces the output:

```
pid = 0
ppid = 28
pgrp = 0
```

28 seems to be the correct pid (calling ps.ttp after running this prg
gave pid 29 for ps.ttp) but is returned by Pgetppid. Pgetpid seems to
return 0 all the time. The pgrp value seems to be ok but I haven't
done much to verify that.

I checked my mintbind.h, the function codes for Pgetpid, Pgetppid and
Pgetpgrp are 0x10b, 0x10c and 0x10e respectively, just as stated in
mint.doc. This happens with MiNT 0.94, I remember having seen it with
0.92 too.

I am using PureC where %d expects a 16-bit int, so it's not a parameter
type problem.

Has anyone encountered that before? Is it a bug in MiNT or in mint.doc
and mintbind.h, or am I just making a stupid mistake?

Thanks for any help...

Ok, if all went well.. I uploaded the background player to Atari.archive into the new directory.

The file is called mplay1_2.lzh and will play .MOD files in the background on an STE with no real slowdown, or on an >>ST<< with some system slowdown. Its not bad, actually.. doesn't even mess up whihile loading a file. It doesn't play with the best quality in the world in the background, but thats the way it goes... :)

Paul - cs331109@umbc5.umbc.edu

> compiler with switchable support for both 16- and 32-bit ints. :-)

LOL! Let's see...I'm out of work, on a diet, and haven't had a life
since I bought this ST in early 1986. I do still sleep a bit. ::grin::

I could change size_t to 32 bits in HCC pretty easily, but most

existing code will break if I do that without also adding full prototype
support. I could just make sizeof(int) 32 bits, but that would sure
make for a lot of ineffecient code, and also would break GemFast totally.

I've been looking around for an ANSI prototype preprocessor/precompiler
that I could add to HSC. I keep finding tools that will convert
prototype/C++ style function declarations and definitions to K&R style,
but I've yet to find a tool that will also insert the crucial recasts
in the parameters of function calls. Without the recasting, converting
prototyped code to K&R style will just break the application.

I'm constantly torn between whether I should try to hack and patch HCC
to grok prototypes or whether I should take Steve's advice and just
throw it all away and start over with an ANSI grammar description and
a yacc-alike tool. Somehow I have a feeling that neither will happen
too soon. ::sigh::

Hi Minters,

how can a program determine what device in u:/dev its stdin and stdout are
connected to? I want to write something like the Unix "tty" command to allow
programs to find out if they run on the console (i.e. they can use GEM calls),
in a mw or bgacc window or on a terminal.
Any ideas how to do that?

Message-ID: <2FF3JB1w165w@tsoft.sf-bay.org>
Source record: 44625

Just a couple of quick questions:
<< REF: Post: 3855 of 3857 >>
Newsgroups: comp.sys.atari.st.tech
From: ilepore@isis.cs.du.edu (Ian Lepore)
Subject: Re: Using a Sony MultiScan monitor
Organization: Nyx, Public Access Unix at U. of Denver Math/CS dept.
Date: Thu, 30 Apr 92 08:32:23 GMT

Question: Does this apply (both monochrome and color) to the original
NEC Multisync ?

2nd question:
I have a Mega STE with 4Mb that I use with a Hybrid Arts ADAP 1
sound editor/sampler. It sure would be handy to expand the RAM beyond
4Mb to hold longer samples. Does the VME slot allow use of additional
RAM ? (And if so, does the Mega STE know how to see it). Of course, if
the the answer is yes, where can I buy one...

Thanks.

I don't think you can with some of the older machines, so the old
ST 520 will have to have the 6 chip set, but the newer machines
have jumpers to let you do this, my STFM 1040 with TOS 1.2 had the jumpers
marked 256/1meg or some thing like that, the 2 chip set is a better option
if you can use it..

Note: not all 2 chip machines have 6 sockets fitted...

1732. Help with sozobon133, make does not work..

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-01 10:40:06 UTC
From: bert@cs.vu.nl
Message-ID: <14244@star.cs.vu.nl>
Source record: 44629

Hello,

I have the following problem: I did installed sozo133i (with install.prg)
Spreaded over 2 floppies I have one directory with bin/ include/ ..
and the other with doc+examples. Seemed as it has to be. But when I
try to make the example hello.c (copied to bin directory) the makefile says:
cc.ttp .. hello.c ..
cc can't find compiler
Ok, I try cc myself but that returns without doing something,
unfortunately it does not have a HOLDSCREEN so the error message
disappears. Then I tried hcc.ttp. That produced a hello.s so that
seems OK. But I do not know how to proceed? In fact I want to use
make. So it comes down to the following:

> Why can't make find cc when I see it is in the same directory?
> Why does cc seem to have a problem with finding himself??
> Must I set path-variables (but I'm using it with GEM)?
> Can make use hcc instead of cc, but how?
> How can I continue with hello.s, using ld?

OK, I thing that when I read the docs maybe I get the problem
solved, but when one of you know an answer to one of the
questions, please email:

bert@cs.vu.nl
Thanks, Bert.

1733. How to emulate color on mono monitor?

1737. MiNT problems.

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-01 13:24:54 UTC
From: hrs@aber.ac.uk
Message-ID: <1992May1.132454.13290@aber.ac.uk>
Source record: 44633

I finally decided to down-load MiNT and have a go at this new extension. Unfortunately I have run into two problems. At the moment I'm only messing about with mint.prg in the auto folder, I am not using any other MiNT related programs. When I boot up two things happen. First my Neodesk fails to start and I end up back at the Atari desk. The most strange thing however, is that the contents of an entire directory called D:\TEX vanish! I have a lot of stuff on a 96 MB drive system and as far as I can make out it's the only one that goes. When I reboot without MiNT everything is OK again. I can repeat this as many times as I like. The other thing to mention is that the Neodesk problem and D:\TEX vanishing are unrelated because I can remove the auto load feature so that I boot to the Atari desktop only and D:\TEX still vanishes.

Other points: I have renamed mint.cnf to mint.cfx so that this is not read by MiNT. The machine I'm using is an STE with TOS 1.6. I get the MiNT message OK at boot up (I'm using 0.94 - the same thing happens to 0.92) and all the new drives are accessible so it appears that MiNT is functioning. Since I use TEX a lot, the fact that D:\TEX goes means that I cannot use MiNT. I have deleted the D:\TEX directory and recopied everything back in without any effect. I'm using an ICD adapter on my HD.

At the moment I have not tried removing all my accessories and TSRs to see if there is a conflict, I shall try again this weekend.

Anybody got any ideas?

Herb

Being a confimed CALAMUS user, I have used CALAMUS 1.09n for years and
recently SL, my only - and from the light of experience - advice is, unless
you want colour output, stick to V1.09n as I have found it to be 99.9999999%
reliable!

Bye for now

One trick that I have found useful when planning to solder to multi-way plugs such as the 13-pin DIN and the 15-pid High-Density, is to buy the mating plug or socket at the same time. Then put the two together before soldering the wires on. The mating part will hold the pins in place and avoid that terrible problem of the pins moving when the heat makes the plastic soft!

I have made up a switch box exactly as described above, and it works very well. I did indeed use a rotary ganged switch, and put a RCA phono socket on the switch box too. I use it with an NEC Multisync 3D.

The main problen I had was finding a model 3D monitor. They have been discontinued here in the UK, and replaced by the 3FG series. These will not Sync down to a 15kHz line rate. I wish manufacturers wouldn't be so blinkered in thinking all the world's a VGA/SVGA PC! :-(

...

>> Why can't make find cc when I see it is in the same directory?
>> Why does cc seem to have a problem with finding himself??
>> Must I set path-variables (but I'm using it with GEM)?
^^^^^^^^^^^^^^^^^^^^^^^^
Yes. The package includes an auto-folder program that sets environment
variables. If you used the INSTALL.PRG, everything should be configured
properly. Be sure that the environment-setting utility is in the auto
folder of your boot disk, and be sure that its data file is in the root
directory of that disk, along with the copy of the DESKTOP.INF file that
was modified by INSTALL.PRG. Reboot. Now you should be able to run MAKE
by clicking on a *.mak file, and all the compiler components will be able
to find themselves.

1746. Vanishing D: \TEX dir

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-01 21:24:08 UTC
From: hrs@aber.ac.uk
Message-ID: <1992May1.212408.9536@aber.ac.uk>
Source record: 44542

Got back tonight and started looking into my missing D:\TEX directory
when I boot up MiNT (0.94) from the auto folder. Took out all ACCs and
autos (except superboot - I know it could be superboot but...) and the
TEX directory still would not respond. So I decided to rename it (had to
rename with MiNT out coz' while MiNT is loaded 'show info' doesn't work)
to something like D:\TEXX. Once I renamed it all my TEX stuff came
back to life. The really funny thing though is when I now rename
TEXX back to TEX (with MiNT loaded) as soon as the new name is
registered (i.e. pressing OK in 'show info') the whole directory
vanishes again! Of course at this point I can't rename it back to TEXX unless
I reboot without MiNT. Strange eh? This effect does not occur on any of
my other drives. I wonder if anybody else would like to try and set up
a D:\TEX directory and see of it vanishes when MiNT is loaded?

Still can't get Neodesk to run when MiNT is on.

In "Using and Porting GNU CC" by Richard M. Stallman, 15 Feb. 1992, for
version 2.0, you can read on page 29:

" -O Optimize. Optimizing compilation takes somewhat more time, and a lot
more memory for a large function."

So the first thing to do if you're running out of memory during compilation
should be to disable optimization.

>are involved, the type is size_t. the type of "sizeof(FOO)" is size_t.
>size_t is always "unsigned long" regardless of 16/32 bit integers
>(controlled by the -mshort option to gcc) (see <compiler.h> and <stddef.h>)

Remember, we were originally (weren't we?) discussing the use of the MiNT libs
with _Sozobon_ C (or Heat-n-Serve, as it's now called), in which size_t is
unsigned int, 16 bits. I'm already working on the long-allocation routines; I
hadn't thought of read()/write() limitations, though. [Hmm, this could get
messy real quick, adding a long-function for everything that uses size_t's.
There's gotta be an easier way.]

>In other words a highlevel cursus-like AES-interface (sounds nice :-)

I've been kicking arond the idea of writing an 'intercept library'
that would take your printf(), fprintf(), getc(), etc, stream functions
and reroute the results to a window. In general, you'd be able to take
any generic text-mode program and link it with this library and it'd
become a GEM program automatically. I have the text output to a window
pretty much coded, but I haven't done anything for the input side.
There are some problems I've yet to deal with; you may end up having to
scatter some Yield()-type calls through the code I think, to get it
to cooperatively multitask with DAs properly.

As to things like putting a boxed message with more than 3 buttons on
the screen, GemFast v1.8 will have functions for that.

Are there any provisions for modeless dialogs in the GemFast library? Unless GEM has been hacked severely, modal dialogs will go out of style very quickly once MultiTOS hits the street (so to speak).

>
>(int)Pgetpid(), (int)Pgetppid(), (int)Pgetpgrp()

This type of problem is very common with printf, especially when you forget what types you are passing. I'm surprised that GFA BASIC supporters haven't yet swamped the news group saying how it could never happen in their favourite language, and rightly so - There is no reason why C compilers shoudn't have a switch to check printf(const char *str, ...) parameters when str is a literal. Purists may complain about consistantcy, but this would only be an option and is nothing compared to the implementation of Pascal's writeln.
For those fairly new to programming in C, here is a list of common mistakes (ones I have made more than 20 times :-)) that are difficult to find (Unless you carry this list in your head):

1) printf types - See example above.
This often causes zeros to be printed when you didn't expect them and other values in the wrong place.
2) a=b when you meant so say a==b
Often causes the condition to be always true (good example here recently)
3) misplaced semi-colon eg.
```
for (i=0; i<100; i++);
printf("Hi there");
```
In this case the printf is only done once.
4) Macros with side effects eg.

```
chr=toupper(getch()); may expand to
chr=(((getch())>='a' && (getch())<='z'):getch()+32:getch);
In this case (which I once wasted hours on, although fortunately I was
being paid for them) you have to hit letters several times for a response
(and the number of times varies on the case of the character).

- Leo Hendry.

1757. MiNT question: How to find controlling terminal?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-03 18:31:42 UTC
From: wr@bara.oche.de
Message-ID: <H.O5&x9VzcV32@bara.oche.de>
Source record: 44553

Hi MiNTers,

How can a process determine the name of its controlling terminal, i.e. of the file its standard input and output are connected to? What I want is something like Unix's tty command. I want my shell profile to be able to determine if it's running on the console (i.e. can use GEM calls), in a bgacc window (i.e. can rely on Cconin returning correct scan codes for function keys) or on a serial terminal (i.e. must use VT52 key codes).

Is this possible at all? If it is, how can it be done?

Thanks for your help

From: wr@bara.oche.de
Message-ID: <H.TsKSMm3QWbI@bara.oche.de>
Source record: 44554

Hi,

That new bgacc is really a great thing, makes mw obsolete imho...
But is it possible to send it commands, e.g. to tell it to run
a specific command with specific options? I'd like my newsreader
to call the editor that way so the editor could run in a window
along with the other news windows.
bgacc might listen to some pipe file for incoming commands (like
that lpq program does). That would really make it a very useful
thing... especially if it did env var expansion and PATH search
itself...

Is that already possible? If not, it should be implemented in one
of the future versions... shouldn't be too hard to do, I guess...

yes it is :-) look at findfile() in findfile.c
/* findfile: given a base filename, a list of directories, and a list
of possible extensions to the filename, attempts to find a file.
Useful for doing, e.g. spawnvp. Note that the current directory
is always searched first! If the filename already contains a
path specification (or extension) then the given path list
(or extension list) is ignored.
Returns the name by which the file was found, or NULL.

> are there any provisions for modeless dialogs in gemfast?

It depends on what you mean by "provisions for". I've been thinking heavily in those directions for the past 6 months, and I've striven to do nothing to prevent them, but I don't directly support them yet either.

The problem with modeless dialogs is GEM itself -- it is very difficult to write 'blackbox' library routines for GEM, because events are handled on a per-application basis, not a per-window basis. This requires the host application to be intimately aware of what the library functions are doing with windows, and "intimately aware of" is the exact opposite of the concept of blackbox objects that you can pull from a library.

I recently did a big writeup on the problems of event handling and object-oriented libraries. I should dig them out and post them here on the net (it's a series of 3 messages). In the messages, I describe what I see as the problems, and propose a couple of potential solutions. I could implement any one of the solutions, but I really would rather have feedback from the whole GEM programming community before I move on it. In short, solving the problem of event handling in library routines is going to require everyone to adopt a new programming style; I don't want to lay a new style on the world single-handedly.

```
> read()/write()...adding a long version of everything that uses size_t

One potential solution is to cover the functions with macros that
contain recasts. Ideally, you s/b able to do:

#define malloc(size) malloc((long)size)

Unfortunately, HSC doesn't -- right now -- implement that ANSI rule that
lets that sort of macro work. But, if you think this could be a viable
solution to the problem, I'll set about implementing that rule in the
preprocessor asap.
```

> territory ... you certainly can't declare an auto variable of that size).

OK, what happens if you do:

```
int bigarray[100000];
...
save = (int *)malloc(sizeof(bigarray));
```

It's conceivable that Sozobon will barf on the declaration of "bigarray".
If not, the malloc will fail anyway. My point is that the malloc
certainly should succeed if the declaration of bigarray does, i.e. if it's
possible to have >64K arrays, sizeof() should be 32 bits.

Does

```
int *foo = (int *)lmalloc(100000L*sizeof(int));
...
foo[99999] = some_value;
```

work under Sozobon? Again, if it does, then sizeof() should be 32 bits
(IMHO; this one isn't quite as clear cut as above). And if it doesn't,
then obviously "lmalloc" is rather dangerous.

Of course, as you point out, this raises all sorts of nasty compatibility
problems with old code that assumes that "size_t" is "unsigned int".
But note that carefully written code that uses sizeof() everywhere and
never assumes anything about sizes of integers should work anyway.
Alas, all too much code is not carefully written :-(.

I guess the easiest way to "fix" Sozobon would be to make integers 32
bits. This would probably be non-trivial to do :-(.

Then, of course, there's the solution of simply admitting "the compiler
doesn't support large data types". Then you get users screaming at you
because they want large arrays; but there's always the GEMDOS Malloc

and Mfree functions...

Thanks to Eric Smith, my D:\TEX now no longer vanishes under MiNT.
The solution (as Eric mentioned in his mail) is simple. The volume
name for drive D: was TeX, evidently this conflics with the directory
called TEX. The solution, rename volume name to something else. Thanks
once again.

Unfortunately I'm still having problems getting Neodesk3 to run under MiNT.
Surely someone must have tried this and solved(?) it?

1764. GEM Programming -- what's next? (1 of 3)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-03 20:10:25 UTC
From: ilepore@isis.cs.du.edu
Message-ID: <1992May3.201025.8249@mnemosyne.cs.du.edu>
Source record: 44559

Well, GemFast v1.8 is about done, and I'm starting to think ahead. I know what v1.9 is going to be like: A lot of work to make GemFast portable to compilers other than HSC, and a few new object types for dialogs. (I keep wanting scrolling listboxes that popdown like the ones in CUA/Windows3.) This is mostly tedium work, but nothing hard or innovative. The main limiting factor is how fast I can write the docs for things I add to the library. Actually, I may have to write a complete replacement form_do handler to implement scrolling list objects, that'll be a little harder than "tedium work".

What's mostly on my mind now is GemFast v2.0. I know, in a vague way, what I want v2.0 to be all about, but I'm not sure how to go about it. As I've mentioned a few times lately, it's hard to write blackbox library routines that use windows, because of the way GEM handles event processing. I want v2.0 to fix that problem.

So what's this blackbox stuff I'm always on about? Let's look at a couple examples... Suppose your application wants to allow users to view a file. There should be a single, simple library routine you can call that will load the text into a window with scroll bars and all. Once your program has called the library routine, it should be able to forget all about it; the library routines transparently handle all window events. Or, suppose you want the user to be able to do a little bit of simple text editing. You should be able to open an edit window with a single call, and the library routines manage all interaction between the window and the user.

GEM manages events on a per-application basis, and we need them to be handled on a per-window basis. Any time the main application does an event wait, a message or event could come in that needs to be handled by a library routine with an open window. The application may not be aware of what the library routines are doing, or even how many windows are open. Does that sound a little odd? Well, the application may know that it created a browser object at some point, but it may not know whether that window is still open or not. And, for that matter, it doesn't even need to know. Since a browser is a read-only item, there's no reason for the browser library routines to involve the main application in the closing of the window. I can go on at great length about the hows and why of object-oriented blackbox routines, but I think I'll skip it for now, and respond to questions anybody has about it instead of babbling gratuitously.

There are two main issues to deal with when you want write event-driven library routines that are blind to the application they're embedded in:

- Dispatching events to the library routines that are responsible for window the event pertains to.
- Managing the list of events to be waited on, depending on the needs

of all currently-open windows.

I have a feeling the second issue is the harder of the two. The next two messages will address these two issues; taking the easier one first.

1765. GEM programming -- what's next? (2 of 3)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-03 20:15:17 UTC
From: ilepore@isis.cs.du.edu
Message-ID: <1992May3.201517.8366@mnemosyne.cs.du.edu>
Source record: 44560

I have several ideas on how to solve this problem of dispatching events to all open windows even when the applicaton isn't responsible for (or even aware of) all the open windows...

Idea # 1:

The main application can do an event wait as usual, and if the event doesn't pertain to it, there can be a way to hand off the event to the library routines. To implement this, I picture a pair of new functions, apl_register() and apl_dispatch(). When a library routine opens a window, it calls apl_register() and passes a pointer to a routine that handles events. The apl_register() function maintains a list of all currently-registered event handlers. When the application receives an event, it passes the XMULTI structure containing the event to apl_dispatch(), and apl_dispatch() passes it to all registered event handlers. Each event handler examines the event data and acts on it if appropriate. If a handler completely handles an event, it clears that event bit in the events-which-occured mask, so that other handlers don't waste time checking to see if they need to handle the event. When apl_dispatch() returns control to the main application, it handles any events that are still pending in the events mask.

This idea has one big factor in its favor: it requires almost no change to existing code. You'll already have an evnx_multi(&xm) call followed by your event-handling code. You just insert apl_dispatch(&xm) following the evnx_multi() and everything works just like it always did. In fact, since evnx_multi() is a GemFast-defined function, not a direct GEM binding, I can even make it happen transparently behind the scenes, by putting the apl_dispatch() call in the evnx_multi() implementation.

But there is also a drawback: what if a library routine needs to do an evnx_multi() call of its own? It might get a message that pertains to a window that the main application opened directly. In the idea #1 scheme of things, there's no way for the library routine to pass that event to the main application. That brings us to...

Idea #2

This is nearly identical to idea #1, except that the main application also uses apl_register() to register its own event handler. Now, the main event loop in the application is reduced to two calls:

```
for (;;) {
evnx_multi(&xm);
apl_dispatch(&xm);
}
```

Everything that used to be in your main event loop is moved to a separate event handling function, and you register that function with apl_register() before going into your event loop. Then, events which aren't fielded by a library routine are automatically passed to your registered event handler. The main advantage here is that library routines can now do an event wait, and if the event is for a main-application window, the apl_dispatch() call will get that event routed back to the main application.

I think this idea has a lot going for it, but it does have one major drawback: your event handler routine has to be reentrant, and that imposes some restrictions on your coding style. (Consider that you could be processing a menu event which opens a dialog box. The dialog handler (which you know little or nothing about) could do an event call and call apl_dispatch(), which could result in re-entering your event handler while it's still handling the original menu event.) Personally, I consider this to be No Problem, because I tend to write routines that are reentrant out of habit, but I'm not sure how it might affect the coding style of others. Especially, if you aren't used to working with reentrancy issues, you can fall into subtle traps.

Idea #3

My third idea is by far the most ambitious, it comes down to basically redefining the standard GEM programming idiom from scratch. In fact, this is probably a GemFast v3.0 kind of thing, but I want to get folks thinking about it. Here, we tie events and windows very closely together. When you open a window, you do it via a call to a library routine, not a direct wind_create() call. You provide a library of callback functions which is attached to the window object the library creates. A central dispatcher function in the library invokes the callback functions as needed. The library also provides a set of default functions that handle the routine window events such as sizing and moving, so a lot of applications will have only a drawfunction actually coded, and the library supplies the rest of the standard window functionality. It should be possible to build up classes of window objects for text-in-windows, dialog-in-windows, pictures-in-windows, and so on, by having libraries of routines that implement standard drawing functions and scrolling functions. When you call PictureWindowCreate(picbuffer, NEO_FORMAT), that routine will call the basic WindowCreate(), and then will supply the proper callback functions for drawing and scrolling a NEO type picture. If your application is a paint program (and not just a picture viewer), then after calling the PictureWindowCreate() function (which returns you a pointer to a Window object structure), you can just plug in a pointer to a callback function to handle button events, and that's your hook to provide the drawing functionality, but the library routines still handle all the other mundane window tasks. In this scheme of things, menu and timer events would be tied to a special "window handle" of 0, so that your main program can handle events which aren't specific to a single window.

I think my immediate goal is to implement a generic event dispatching system that is compatible with idea #3. That is, I want to provide a foundation which #3 can be built on, without forcing the world to relearn

everything they know about GEM programming right away.

I do know that if the state of available software in the ST world is to improve, then building GEM applications has to become much easier than it currently is. The two best ways I know of to make it easier are to move towards object-oriented programming (not C++ mind you, just OO design), and then to begin coding libraries of pre-built objects which you incorporate into your applications with just a simple function call or two.

1766. GEM programming -- what's next (3 of 3)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-03 20:23:16 UTC
From: ilepore@isis.cs.du.edu
Message-ID: <1992May3.202316.8459@mnemosyne.cs.du.edu>
Source record: 44561

Now we come to the difficult issue...how to manage which events to wait for when blackbox library routines have windows open.

Let's suppose you have an ideal application. It has a menu bar, and an event handler to process menu selections. It conducts a few custom dialogs. And, it relies heavily on libraries of prewritten windowed functions so that it doesn't have to do any window management itself. From the main application's point of view, it needs to worry only about message events so that it can process menu selections. But, when windows get opened by the library routines it calls, those windows may need to respond to mouse events, keyboard events, and so on.

In the prior message, I posted 3 ideas for handling the dispatching of events to all registered event handlers. Two of those ideas have the main application doing the event wait, and thus only the main application can set the mask of events to wait for in the evnx_multi() call. The third idea has windows and events tied closely together, and managing the events to wait for actually becomes pretty simple: each window object has an event set associated with it. The event set for the top window is used as input for the evnx_multi() calls. (It's a bit more complicated than that, but not much.)

In the other two scenarios, we have a bit of a problem: how can a library routine which opens a window communicate its events-oriented needs to the main application? That is, if the application doesn't care about keyboard events, but it opens an editor window, how is it to know that it then must begin waiting for keyboard events too? Another problem is how to (or even whether to) multiplex conflicting events. For example, what do you do when the main application and a library window routine both want to use MU_M2 events?

As usual, I have ideas, but no firm answers. The first idea I have is to make a few rules that prevent conflicting events. Looking at each type of event, I propose this:

MU_BUTTON - A wait for a single or double click, with an mbstate of
button-down, can be used by main and library routines. A
wait for button-up can only be done modally, by the
owner of the current top window.
MU_MESAG - Can be used by main and library routines. In addition,
this is a required event at all times except when
running modally.
MU_KEYBD - Can be used by main and library routines.
MU_TIMER - Reserved for main routines when non-modal.
MU_M1 - Reserved for main routines when non-modal.
MU_M2 - Reserved for library routines; owner of top window only.

I've made a couple references to "running modally". By that, I mean that the library routine or main application has done a wind_update() call to lock out window changes or system mouse handling. When an event handler detects its window is on top, it can "go modal" and then safely do most anything it wants, event-wise, because another window can't be topped while it's modal.

So, any number of routines can wait for button-down concurrently, because the event will only pertain to one window. When a button-down event occurs, every event handler can check to see if its window is on top, and ignore it if not. Also, any windows that don't care about button events can just flat-out ignore the event even when their window is topped. But, nobody can wait for button-up unless they go modal, because it would impossible to have one window waiting for button-down and another waiting for button-up. The same sort of logic applies to keyboard events.

Timer events and mouse rectangle events are problematic, primarily because they are independant of the current top window. Logic to multiplex conflicting timer events is beyond the scope of the rather simplistic dispatchers I'm proposing. So, it seems easier (for now at least), to just say: library routines have to live without timer events, except when running modally. Since two rectangle events are available, it makes sense to reserve one to be totally under the main application's control, and the other to be shared among the library routines. When sharing the M2 event, some sort of logic is needed so that the owner of the current top window can dictate the rectangle to watch. This smacks of dispatching idea #3, so for now I just want to reserve the event for future implementation.

Message events are the simple one: the main application alway includes messages in the set of events it waits for. This shouldn't be any problem, since all useful applications pretty much need message events anyway.

Okay, now we have some (perhaps flawed?) rules, but if the main application is going to wait for events on behalf of library routines it knows little about, then there has to be a way for library routines to tell the main application what they need. I can think of several schemes to do this, and some pros and cons for each scheme. But, what is done to solve this problem is going to depend heavily on which of the 3 dispatching solutions is in use.

It is at this point in my thinking that I usually begin to think that dispatching idea #3 really has a lot going for it, and I think that idea #1 can be trivially rejected as being too inflexible for growth. Since #3 has been locked out as too complex to do right now, that leaves #2. Actually, a varient of #2 is probably what we need.

First, let's modify the main loop concept in dispatching idea #2 a bit: instead of the main application calling evnx_multi() then passing the XMULTI along to apl_dispatch(), let's eliminate the evnx_multi() altogether. The main application registers its event handler using apl_register(), and it passes a pointer to its XMULTI at that time. The main application can change the contents of its XMULTI structure any time it wants to, subject to the rules above (ie, don't touch MU_M2-related

data, and so on.) It also passes a flag to apl_register() that says "I am the main application." Then it calls apl_run() just once, and that function never returns.

When a library routine registers an event handler, it also passes an XMULTI that says what events it wants, and a flag that says it is NOT the main application. The apl_run() routine merges the events from all the library routines that are registered into the main application's XMULTI, then it calls evnx_multi(), and uses apl_dispatch() to send the events out to the main application and other registered handlers.

Well, I think that's enough babbling for now. It should be clear to all and sundry that I have given this matter some thought, but probably not enough thought. But, my poor little brain becomes overheated when it works on these problems for too long, and I'm to the point where I really need more input. I need to know whether other folks have considered these issues. Have any solutions, partial or complete, been cooked up? What problems do you foresee that I haven't event touched on here? What do we do next?

The answer to "does it work" is "yes and no". If 'foo' is a char
type, this will always work. If 'foo' is any type where sizeof(foo[0])
is greater than 1, it will work if you use the optimizer, or break if
you don't.

The reason is that the code generator, in processing the array subscript,
generates a bogus sequence of:

```
move.l #sizeof_on_array_item,d0
muls your_index_value,d0
ext.l d0
```

Naturally, when the result of the multiply is > 64k, the ext.l wipes
out the high-order bits of the result, and you get bogus indexing into
the array. The optimizer is aware that EXT is never needed following
a MULx instruction, so it removes the ext; then everything works fine.

The internals of HCC are so ugly, that in two years of looking, I
still can't find the place in the code generator where I need to tweak
it to eliminate the EXT instruction. Until I find it, the rule is:
if you have arrays bigger than 64k (that is, sizeof(array) is > 64k,
not 64k elements in the array), then ALWAYS use the optimizer.

> make HSC sizeof(int) 32 bits

Actually, it might be trivial, I think there's a constant in a heder
(er, header) file I could change that would fix everything at once.
(I've never tried). But, a complete library rewrite would be needed.
Code would be a lot less efficient. All existing GEM code would break.
I do remember looking once to see if it could be made command-line
switchable (sizeof(int) that is), and that is NOT trivial.

1770. Spectre 128 on TT

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-03 22:05:51 UTC
From: sander@krazykat.engin.umich.edu
Message-ID: <#px+7J#@engin.umich.edu>
Source record: 44565
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I just bought one, runs great on my TT. The problem I am having, however, is porting Mac applications to the darned thing.
I have AccessPC, which works fine for documents, but the applications and their resource forks seem to mess it up. This would not be a problem if I had BinHex on the spectre partition, but alas, it is not so. I attempted to port a Stuffed file over, to see if archives would survive the port, but this did not work either, even after I reset the archives creator resource to 'SIT!'. Unstuffit still won't recognize it as a stuffit archive.

Any suggestions? Am I correct in assuming that attempts to modem files from a mac will run into the same binary vs. hex problems? How do I get the durned BinHex appl. over?

thanks in advance...

In my ACICS libaries, although not OOP'ed, I designed several source
links that people can include into thier source app when compiling
with event_multi().

Its a way for people to provide thier own event background functions by
providing a simple source level solution.

The problems, you might have experienced too, in sharing data, or transmitting
information between events with such a event based library I solved by
including two event calls for filling and emptying a common app communication
buffer of unsiged bytes 1K in length. Certain sections of the buffer are
write protected during any calls to the included standard routines I have
provided like, VT52, ANSI emulation cursor position resgisters, window
bounds etc.

Disadvantages I have found:

The problem I have been trying to figure out with such pre packaged routines
is the fact that when the apps programmer decided to write out his own event
routines, he in fact can over write certain areas of the communications
buffer without knowing it. In effect, trying to provide the greatest amount
of freedom without compromising the communications control registers
reserved in the ACICS 'systab' structure is a major problem I haven't
been able to ovecome.

The only solution would be to provide only one set of routines for a limited
set of functions I can think of myself for a person to use and hope it covers

the arena of applications he or she has in mind...even a worse solution
in my opinion.

Since I am actually a liberal programmer, I also provide behavior controls
for certain functions for example: my login function:

```
int vt_login(void)
{
unsigned char d_c_b[5];

d_c_b[0]=systab[17];
d_c_b[1]=systab[18];
d_c_b[2]=systab[19];
d_c_b[3]=systab[20];
d_c_b[4]=systab[22];

wind_set(0,0,0,24,0);

vtmoutf("%C");
vtmout_xyf(0,0,"%s","ACICS - New User Application");

switch(systab[100])
{

case VT_52: vtmout_xyf(73,0,"%PVT_52%Q");
break;
case ANSI: vtmout_xyf(74,0,"%PANSI%Q");
break;
}

/* Well we have a formatted display here so we are going to have kill the
system window....a rather laborious task but easy enough....*/

vtmout_xyf(0,3,"%PName:%Q");
vtmout_xyf(49,3,"%PAddress:%Q");
vtmout_xyf(0,4,"%PCity:%Q");
vtmout_xyf(49,4,"%PState:%Q");
vtmout_xyf(0,5,"%PZip:%Q");
vtmout_xyf(49,5,"%PPhone:%Q");
vtmout_xyf(0,6,"%PPassword:%Q");
vtmout_xyf(49,6,"%PScreen width:%Q");
vtmout_xyf(0,7,"%P--------------------------------------------------------------------------
-------%Q");
vtmout_xyf(0,8,"%PLot:%Q");
vtmout_xyf(49,8,"%PLod:%Q");
sys_date(s_date);
sys_time(s_time);
vtmout_xyf(5,8,s_time);
vtmout_xyf(54,8,s_date);
vtmout_xyf(0,9,"%P--------------------------------------------------------------------------
-------%Q");
vtmout_xyf(0,17,"%P-UI
Window-----------------------------------------------------------------------%Q");
```

```
pos_cursor(6,3);
systab[10]=7;
do
{
p_str(user.name,24,FALSE);
if (srch_em(user.name))
{
vtmout_xyf(0,19,"The name %s is already in use, pick another.", user.name);
user.name[0]=0;
vtmout_xyf(6,3," ");
pos_cursor(6,3);
}
}
while ((strlen(user.name)==0)&&(strcmp(user.name,"NEW")==0)&&(c_detect()));

pos_cursor(58,3);
systab[10]=7;
do
p_str(user.address,23,FALSE);
while ((strlen(user.address)==0)&&(c_detect()));

pos_cursor(6,4);
systab[10]=7;
do
p_str(user.city,13,FALSE);
while ((strlen(user.city)==0)&&(c_detect()));

pos_cursor(56,4);
systab[10]=7;
do
p_str(user.state,2,FALSE);
while ((strlen(user.state)==0)&&(c_detect()));

systab[10]=2;
pos_cursor(5,5);
do
p_str(user.zip,5,FALSE);
while ((strlen(user.zip)==0)&&(c_detect()));

user.phone[0]=0;
vtmout_xyf(56,5,"(XXX) - XXX - XXXX");
pos_cursor(57,5);
systab[10]=2;
pnocr_str(area_code,3, FALSE, 13);
pos_cursor(64,5);
pnocr_str(prefix,3,FALSE, 13);
pos_cursor(70,5);
pnocr_str(suffix,4,FALSE, 13);
strcat(user.phone,area_code);
strcat(user.phone,prefix);
strcat(user.phone,suffix);
```

```
pos_cursor(10,6);
systab[10]=7;
do
p_str(user.password,12,FALSE);
while ((strlen(user.password)==0)&&(c_detect()));

pos_cursor(63,6);
systab[10]=2;
p_str(user.columns,2,FALSE);

init_user();

wind_set(d_c_b[0],d_c_b[1],d_c_b[2],d_c_b[3],d_c_b[4]);
set_up();
upd_sysw();
vtmoutf("%C");
return(TRUE);
}
```

If you will notice, systab is the externalized communciations buffer
that has particular fixed locations that perform certain functions
vtmout(), wind_set(), p_str().

Setting systab[10] to a io control code, like 10, will tell all io
operations to accept all characters, likewise setting systab[10] to
1 will restrict input to numeric only. This eliminates excess control
code that isn't nessacary...ie, don't have to check if input is not a number.

Also, not shown, is the control locks for all these routines which
have dual output streams, to screen or selected RS232C ports.

So whats the deal? The deal is, trying to figure out the ease of use
and flexibility of simple location switches which can do quite powerful
and desirable things, like setting input control above, and HOW to do it.

All of these functions and thier behavior have one common function.
Even_multi() since most of the time in communication situations involve
a lot of waiting. While the system is waiting it can be doing other things,
preferably what you have in mind. This gives the applications programmer
the ability not only what to determine WHAT to do with his time but HOW to
spend his time the way he sees fit.

><Biased toward Bullwinkle cartoons>

Event based programming systems is what I am doing as my senior thesis.

And my MEGA STE is my guinea pig.

If anyone else has had any problems with data sharing, or have introduced different priotrities in their designs I would love to discuss it!

All of these are excellent options.

Problem is here, is we are talking about GEM. Most of the changes you propose
are available in other GUI's.

Another fact I would like to point out is the debugging procedures for
event based systems.

Event based systems are complex because so many things are happening, typically
on one level, or multiple levels.

Some of the concerns I pointed out about accessability of certain internal
information and the ability to modify this behavior would be something
that would be useful in:

1) Upgrading GEM's GUI libraries to be more flexible, with the ability
to be more modern...(X designing custom widgets...) better font handling,
postscript support.

2) Some sort of event_multi switch for providing debugging information.

Nice suggestions though.

The Standard is 0.75 volts into 75 ohms...

The Atari ST/STE puts out 1.0 volt, I have seen this overload
some monitors...

Check your monitor specs...

This is the official Press Release regarding the merger of Z*Net and
Atari Explorer forming Atari Explorer Online Magazine. The first issue
will debut May 1, 1992.

FOR IMMEDIATE RELEASE-

Contact:

John Jainschigg 718-545-2900 GEnie: EXPLORER CIS:76704,1616
Ron Kovacs 908-968-2024 GEnie: Z-NET CIS:75300,1642
Bob Brodie 408-745-2052 GEnie: BOB-BRODIE CIS:70007,3240

April 24, 1992 - Atari Explorer Announces New Online Magazine!

Sunnyvale, CA.- Atari Corporation and Rovac Industries are proud to
announce a brand new online magazine for the Atari Community: Atari
Explorer Online. Atari Explorer Magazine, the Official Atari Journal,
is now extending its coverage of all things Atari to the online scene,
as well. The first issue of the Explorer Online is set for May 1, 1992,
and the magazine will appear biweekly, thereafter.

"Explorer Online will team up some of the finest journalists in
the Atari Community!" said John Jainschigg, Publisher. "We're excited
to be able to offer such a quality product to our many customers. The
goal of Explorer Online will be to serve the needs of all Atari
users: Portfolio, Lynx, ST/TT, and 8 bit. All of Explorer's regular
contributors will be represented in Explorer Online: from music experts
like Craig Anderton, to Portfolio Wizards like BJ Gleason. And we are
actively soliciting contributions, both to the online magazine, and to
our regular, bimonthly print edition. We want to make Explorer Online
a solid resource for the whole Atari community."

Atari has teamed up with Ron Kovacs, publisher of the Z*Net Newswire
and Z*Net Online Magazines, to produce Atari Explorer Online. "When
we decided that we wanted to do an online magazine, it just didn'er is one of
the finest magazines on the market, and it's very flattering to our
efforts that Atari has chosen us to help them with their online
magazine."

"When Explorer Publisher John Jainschigg came to me with an idea for
a new online magazine, there was no question that we were going to
need some outside help. And it was an easy choice to decide where
that help should come from. Week in, week out, Z*Net has provided
the latest news to the Atari Community for years. Indeed, Z*Net has
experienced growth over the years. They have the experience in
launching new online publications, like the original ST-Report,
ST*ZMagazine, and Z*Net PC. Additionally Z*Net's Atari News Service

has appeared in print publications world-wide including: STart
Magazine, ST-World Magazine, ST-Informer, ST-Journal, ST-Express,
AtariUser, Current Notes, and Germany's PD Journal now Atari Journal.
It really just made sense from every side that we considered to ask
them to be involved," stated Brodie."

AEO will be distributed worldwide on major information services and
networks. Atari Explorer Online will carry up-to-the-minute reports on
hot topics in the Atari market: from trade shows to new product
announcements. Explorer Online will give you the facts you need to make
the most of your Atari investment. Utilities and Atari PD releases, new
product demos, product and dealer databases, and other interactive
offerings will round out the publication, making Atari Explorer Online
the best in online journalism today!!

_
Jon Clarke o( ) The Z*NET International Gateway in New Zealand
Voice:(+64)25-962638 / /\ jonc@status.gen.nz 3/772:105 GEnie: J.CLARKE6
::Z*NET a free ascii based magazine for all computers, distributed globaly::
========--

t
make sense to completely re-invent the wheel," stated Bob Brodie, Atari's
Director of Communications. "In the online Atari community, Z*Net has
set the standard for quality and accurate reporting, and it only made
sense to invite them to participate in this new venture. Ron Kovacs and
John Nagy are among the finest, most dedicated journalists on the Atari
scene today. The entire Z*Net staff will be part of the new team at
Atari Explorer Online. We're very excited that they have chosen to join
us in making Explorer Online the best it can be."

The start of Atari Explorer Online also signals the end of the Z*Net
Online magazine for the Atari ST Community. Current plans call for
Kovacs' firm, Rovac Industries, to continue to publish their popular
Z*Net PC, and Z*Magazine publications. "While there is a certain
sense of loss with Z*Net discontinuing, we're very excited that Atari
has invited us to be a part of this exciting new venture" said Ron Kovacs,
Editor-in-Chief of Atari Explorer Online. "Atari Explor

1775. Re: GEM programming -- what's next (3 of 3)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-04 08:04:16 UTC

Message-ID: <klamer.704966656@mi.el.utwente.nl->
Source record: 44570

Since Ian requested to do this in public instead of by private mail,
here i go:

In <1992May3.202316.8459@mnemosyne.cs.du.edu-> ilepore@isis.cs.du.edu (Ian Lepore) writes:

First of all, let i tell that i already wrote some idea #3 type code.
This should be a general usage type library, not too heavy copyright
protected (GNU-like). I have it running in prototype (i.e. alpha) phase.
Scrollbar handling is the major part which is planned in, but not yet
implemented (let alone tested... ;-)

-> In the prior message, I posted 3 ideas for handling the dispatching of
->events to all registered event handlers. Two of those ideas have the main
->application doing the event wait, and thus only the main application can
->set the mask of events to wait for in the evnx_multi() call. The third
->idea has windows and events tied closely together, and managing the events
->to wait for actually becomes pretty simple: each window object has an
->event set associated with it. The event set for the top window is used as
->input for the evnx_multi() calls. (It's a bit more complicated than that,
->but not much.)

Hmmm. I missed the rest of the complexity. I didn't miss some of the bugs
in the original evnt_multi() call, though. (Does anyone have these listed?)
The bugs came in on mixed events (from memory: waiting for all kinds of
mouse button events and messages says there is a mouse button event on each
message -- too bad!)

-> In the other two scenarios, we have a bit of a problem: how can a library
->routine which opens a window communicate its events-oriented needs to the
->main application? That is, if the application doesn't care about keyboard
->events, but it opens an editor window, how is it to know that it then must
->begin waiting for keyboard events too? Another problem is how to (or even

The solution is to kick this request to the library dispatcher, which will
do another kind of evnt_multi() then.

->whether to) multiplex conflicting events. For example, what do you do when
->the main application and a library window routine both want to use MU_M2
->events?

Easy one -- multiplex them. I now can have as many MU_M? request as i want.
(And i need them for my button handler in dialog windows!)

My approach here is basically different -- i make everything needed
available to each window needing it. Yes, this does mean a lot of re-writing
of AES internal class code!
An exception to the general scheme must be there for programs who want to

have the complete desktop for their own (like a program which makes a
screen dump of a user-selectable part of the screen -- at that moment
it should be possible to let only this program have the mouse events!)

-> Timer events and mouse rectangle events are problematic, primarily because
->they are independant of the current top window. Logic to multiplex
->conflicting timer events is beyond the scope of the rather simplistic
->dispatchers I'm proposing. So, it seems easier (for now at least), to just
->say: library routines have to live without timer events, except when
->running modally. Since two rectangle events are available, it makes sense
->to reserve one to be totally under the main application's control, and the
->other to be shared among the library routines. When sharing the M2 event,
->some sort of logic is needed so that the owner of the current top window
->can dictate the rectangle to watch. This smacks of dispatching idea #3, so
->for now I just want to reserve the event for future implementation.

I have this already running -- with idea #3.

-> Well, I think that's enough babbling for now. It should be clear to all
->and sundry that I have given this matter some thought, but probably not
->enough thought. But, my poor little brain becomes overheated when it works
->on these problems for too long, and I'm to the point where I really need
->more input. I need to know whether other folks have considered these
->issues. Have any solutions, partial or complete, been cooked up? What
->problems do you foresee that I haven't event touched on here? What do we
->do next?

->--
-> < OK TO PORT >
->This information comes from the atari.st conference on
->BIX (r), the BYTE Information Exchange.

->For additional information about BIX, call 800-695-4775
->or 617-354-4137.
->--

->- Ian

-> (PS: PLEASE DO **NOT** RESPOND TO THESE VIA MAIL!!!
-> For two reasons: first, I have a mail disk usage limit on
-> this system, and second, we need (IMAO) PUBLIC discussion
-> of these issues.)
->

Now my position: I do not have much time left for ST software development.
If anyone waits for me to finish it, he probably will have a perfect
library on an antique machine (by that time ;-).

However, if people are really interested, i might considering releasing
my current code. Or better, share it with some others who are also willing
to produce a public available (note: not PD) source level window library
for the ST.

>recognize it as a stuffit archive.
>

You also have to set the TYPE resource string matching the StuffIt archive identifier. So enter your control panel, AccessPC, make an entry ".sit" and click into the MacApp... button. Then choose StuffIt and select the apropriate icon for StuffIt archives, I think it was SIT! for TYPE and CREATOR as well. I can ensure you that it just works fine.
For .hqx encoded files, I set up TEXT/SIT!, and StuffIt will be launched if I double-click any imported .hqx file.

Regards,
Markus.

1778. /bin/sh compatible shell available for MiNT

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-04 10:24:36 UTC
From: neuhaus@vier.informatik.uni-kl.de
Message-ID: <neuhaus.704975076@vier>
Source record: 44573

Hi all.

I have retrieved the /bin/sh compatible shell from the 4.4BSD distribution, and ported it to the ST under MiNT 0.93. (This shell is also referred to as ash, because the its author is Kenneth Almquist.)

The port was rather trivial, since MiNT is so like BSD. All I had to do was to change the code in exec.c to look for the executable suffixes, and do some CR elimination. I have since written a dump script to dump my hard disk, which uses gawk, sed, tar, compress, backquotes, pipes, traps, user-defined functions and so on, and it works just fine. The shell was compiled with gcc 1.4 and GNU make. The executable, when stripped, is about 90K. However, the shell port should be considered beta for the following reasons:

* Somehow, when using absolute path names like /bin/ls, the suffix search isn't performed, although typing plain ls works just fine.

* When using backquote substitution, CRs don't get stripped as yet.

Also, MiNT does not support the #! feature, so if you have a shell script or a makefile that uses one, you'll have to prepend `sh'. In other words, where unix says `script', you say, `sh script'. The shell can emulate #!, so scripts called from sh *could* work, were it not for the fact that they don't have executable permission :-(.

Otherwise, the port works fine. I will make available a source distribution in comp.sources.atari.st, if

a) many people send email with the words `get /bin/sh' in the subject line; message body will be ignored. If you want to send mail, please read the message just before my .sig.

b) somebody tells me how to post to a moderated group like comp.sources.atari.st.

If there aren't enough people for a source distribution in comp.sources, I can still mail them to those of you who are interested, or can upload them onto our local ftp server.

Included in the distribution is a version of /bin/test, a.k.a /bin/[, that I hacked together within half a day or so. It should behave according to the specs.

Thank you, JRB and ERS for the gcc ports and the excellent libraries, and to ATARI for releasing such a bad OS that it inspired ERS to give us MiNT.

Have fun, and please read the following:

If you reply, please send mail to neuhaus@informatik.uni-kl.de, not
neuhaus@vier.informatik.uni-kl.de. This is a bug in our news software,
and I'm not sure when we'll get it fixed. Thank you.

As people asked me to, I put up Mplay 2.1 at Atari.Archive. Look for..

/atari/sounds/players/mplay2_1.lzh

(or something similar.. :)

Its not my program, but if you have an older ST (no E, sigh..), than it will play .MOD music in the background. Its not the best quality in the world, but it gets the job done...

> my current code. Or better, share it with some others who are also willin
> to produce a public available (note: not PD) source level window library
> for the ST.

Thanks anyway, but my current plans for GemFast and everything related to it are to keep it as a 100% public domain package with absolutely no strings attached. I absolutely abhor the GNU copyleft BS. In my mind, you should either copyright your product and sell it commercially, or place in the public domain with no strings attached. (There are strings attached to HSC only in that it's based on a work that originally had some strings attached, and I follow their recommendations.)

My goal is to improve the state of GEM programming on the ST machines, not to get rich doing it, or even to prevent others from getting rich using my work. If someone does get rich, I don't want a slice of the pie, I just want to see it cause higher sales of ST machines because of great new software available for them. That benefits me, and all the rest of the ST community.

(I've kicked around the idea of asking for a few dollars contribution for GemFast. Even if I do that, it'll be purely voluntary, and the sources and binaries will remain fully PD.)

Source record: 44579

I think that Ian's idea #3 (basically, object oriented programming) is definitely the way to go. The main application doesn't do an evnt_multi at all, or it does so only "modally". Instead, there should be a library "evnt_loop" call that fields events and dispatches them to the appropriate windows. To create a window, the application would do:

```
#include "windowlib.h"
WINDOW *newwindow;
newwindow = CreateWindow(some parameters)
```

The "window" structure would have pointers to functions that would be called for each kind of window message possible, an perhaps also a single rectangle and a function to be called if the mouse enters/exits that rectangle and the window is on top. Default functions would be provided, of course, but the programmer can always override them to create special-behaviour windows.

The benefits (in terms of ease of use) are immense. This is the style of programming that I use now (well, whenever I use GEM :-)) and it's *really* nice to be able to open a window and just forget about it!
Of course, building the library requires some considerable investment.

Source record: 44580

I also am interested in this, and I am currently trying to make a library
for g++. I think this is the most obvious way to go, for it really is
obect oriented techniqus one should use to program windows (IMHO).

I currently have implemented pices of code for windows containg a dialog,
and windows that are used only for text.
eks.
```
Window *aWindow, *anotherWindow;
aWindow = new TextWindow(parameters... );
anotherWindow = new DialogWindow(parameters ...);
```

and some central loop to handle redraws and events...
It's in a very early stage right now, but it's evolving...
(We really WILL need some kind of DialogWindow routines anyhow
as soon as MTos is here for everyone...)

I'll post as soon as I get some real things going.

Erling.

> Unfortunately I'm still having problems getting Neodesk3 to run under MiNT.
> Surely someone must have tried this and solved(?) it?

> Herb

The Neodesk Loader (neoload.prg) must be started before neodesk can run.
This program must be run from the /auto folder, before MiNT starts.
I have heard that you can run it from mint.cfg, but I have not tried this.
The easiest method to accomplish this is the Neodesk "reorder" function.
This is one of my favorite features in Neodesk 3. Use it to make sure that
neoload is run before MiNT.

If you are fortunate enough to have TOS 1.4 or higher, set up Neodesk to
auto-execute. This way, when you issue the "gem" command, Neodesk will
start automatically. Neodesk 3 has been compatible with MiNT since
MiNT release .7 or .8. I have my skull icon for "kill.ttp" and a door icon
for "bg.ttp" After all, if a desktop has windows, it should also
have a door. ;-)

If you have any other problems with this, just send me email.

From: gertjan@kompas.prl.philips.nl
Message-ID: <5495@prles2.prl.philips.nl>
Source record: 44585

A ACSI - SCSI problem:

I have built a SCSI host adapter for my atari ST and it doesn't work well.
The schematics I used were the ones suggested by the Atari Corp. and I checked
everything with a logic analizer. The harddisk I use is a Quantum LPS52S.

What goes wrong is: the harddisk becomes selected and reads the six command
bytes. But he never gets into the data phase, and goes directly into the status
and message phase. So as far as I can see is the ACSI and SCSI protocol handled
in a good way, but my harddisk doesnt understand the commands. I used the
commands: test drive ready, request sense and read block.
The harddisk works on other computers very well.

What am I doing wrong?? I think I overlook something very obvious.
Please answer me by email: gertjan@prl.philips.nl

Thank in advance!

It shouldn't. These values can (and will) be different from the window
size. There are a lot of alternatives:

- Use the environment variables that Gemini sets up.
- Use termcap.
- Under MiNT: use the appropriate file control function on the tty handle.

>Beside how are you supposed to name a program that allows parameters to be

Good point. But that means that there *should* be such a way, not that
there actually is one.

Message-ID: <92126.044502JJL101@psuvm.psu.edu>
Source record: 44589

I am about to take the gemfast plunge, and have what may be a obvious question, the docs (for 1.7) say there is no need to code in ptsin, etc arrays for certain vdi calls, my question then is how should the call be made? a v_opnvwk() call then gets what arguments? Am I missing some thought here?

Also, I have the entire library (or at least the important ones :) of Abacus books, the Professional Gem 'book', and old Atari Developer docs, and am just beginning to work with GEM. I am fairly proficient in C, and want to add gem programming to my programs. I have went over numerous prog sources (CLED, mandlbox, and the sozo133 examples) and have so far been able to open a window, draw in it, create menu bars, dialouges etc.. I think I am moving right along, but I am concerned that perhaps a lot of the coding I am doing is not necessary due to the improvements gemfast makes, and simply want to gather as much of this info up before I start on a 'project'. Can anyone point me to a good source listing for a program that uses the calls associated with gemfast? (Best learning is by perusing code!) I am also interested in seeing code that handles windows that contain vdi drawn graphics, as this is the point that I am now at in my learning. My eventual goal is a gem application that will investigate some of the mathematical graphics in many of Clifford Pickovers books. (I know , slow in C, but at first I plan to concentrate on areas that are not THAT numerically intensive.)

Thanks for any info!

My (non-Mega) STe has 2 rows of 8 solder pads near the ROM chips. Are these the equivalent of the Mega DIP switches? Could I put in the Atari HD disk upgrade if I jumpered no. 7, or is there extra circuitry involved?

If you get any info on this I'd like to know aswell, perhaps you could mail
to the news group?

I've a question about the 1426. Am I right in believing that the stand
now fits properly on top of the TT?

> provided, of course, but the programmer can always override them to
> create special-behaviour windows.

My brother Ken owns one of the original 3B1 AT&T Unix PCs, which came
with a window manager, implemented as a file system. Recently, I took
a look at WINDOW(7) in the manual, which described windows being opened
via a call like:

window_handle = open(wfd, ATTRIBUTE_BITS);

Object-oriented programming may be the way to go, but not everyone has
the system resources to run G++ on their STs. One alternative could be
a loadable window file system which uses GEM. GEM windows could be
created as files on U:\WINDOW and you could write text to them just as
to a regular file.

Such a file system could be created with G++, by some kind soul with
a cross-compiler. Thus, programmers using standard C could have access
to the object-oriented features of a C++ library.

1806. Question about v_gtext() reverse video

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-06 08:30:32 UTC
From: tony@microware.co.uk
Message-ID: <952@mwuk.UUCP>
Source record: 44503

Hi,

I am writing text into a window using v_gtext(). I use vst_color() to set the color, and vswr_mode() to set the writing mode to MD_REPLACE. No problem so far.

How can I write text in reverse video in one replace-type operation? I can do it by writing normally and then putting a v_bar() over the top in MD_XOR mode, but I would like to be able to do it directly using v_gtext() in a single operation. Is it possible? I can't believe it isn't, but I couldn't find a suitable setup function.

Thanks in advance,

Tony.

Source record: 44504

I am thinking of upgrading my ST's TOS (I own a 1040STF with 4Mb RAM and 100Mb hardrive) from version 1.0 to 1.4. I was ready to ring up Evesham Micro's today and order it straight off but I've had been reading some disturbing things about it that put me off.

First off, I was looking through a archive list and I saw a few TOS 1.4 bug fixes (bugs !#?!).

Secondly I discovered that the loading programs into memory is still slow on TOS 1.4 unless you set the FastLoad bit on the program. I currently use PINHEAD to speed things along.

I use NEODESK3. Do you think that a TOS upgrade is really worth it ?

While G++ makes object oriented programming "easy", it's certainly possible
to do OOP in any language. I don't have G++ on my system yet; what I do
instead is to use plain old C, and use pointers to functions to
implement "methods". For example, to tell a window to redraw a part of
itself, I say:

```
WINDOW *win;
...
(*win->draw)(win, x, y, w, h);
```

There are also functions like win->topped, win->closed, etc. The library's
main event loop automatically calls the appropriate window function when
a message is received for a window.

Similarly, there's a MENU structure that has a list of menu entries,
keyboard equivalents, and the function to be called when the user
selects the menu/presses the key. The library automatically takes care
of looking for MN_SELECTED events and checking keys pressed to see if
they represent a menu item.

Not a bad idea, but in practice MW or BGACC provide this functionality
(albeit not so elegantly).

```
WINDOW *win;
...
(*win->draw)(win, x, y, w, h);
```

This is a good start on object oriented programming, but it still leaves inheritance difficult to implement, as you have to duplicate the layout of the WINDOW struct within any class that inherits from it. And, IMHO, inheritance (the IS-A relationship) is one of the most important techniques of object oriented software design.

g++ is large, but I can compile with g++ 1.40 on my 2.5M ST. I'd like to see a good GEM class library, as I don't want to have to reinvent the wheel with my own. After all, code reuse is supposed to be a benefit of OOP.

From the Holy Book of <1992May3.195009.8002@mnemosyne.cs.du.edu>
as spake by ilepore@isis.cs.du.edu (Ian Lepore) :
[I was talking about:]
> > read()/write()...adding a long version of everything that uses size_t

> One potential solution is to cover the functions with macros that
>contain recasts. Ideally, you s/b able to do:

> #define malloc(size) malloc((long)size)

The only problem I can see is the possibility of getting at the function behind
the macro's back, like:

void *(*fred)() = malloc;

Can a conforming program expect this to work? (Yes, I know HSC isn't ANSI, but
there's no point in deliberately making it _more_ difficult to become ANSI).

Prototypes would be the real answer here (as though our wish list weren't long
enough :-( ).

And for a little inheritance you could go like this:

typedef struct _method
{
struct _method *next;
int (*func)();
} method;

WINDOW *p;
method *q;
...
p->draw = inherit( p->draw, newfunc); /* *1* */
...
for( q = p->draw; q; q = q->next) /* to actually redraw */
(*q->func)( p);

*1* At this point newfunc, will be the first function to be called, and all
the previous ones afterwards.

I actually use that style for menu items. (har)

>No, it is not possible at this time. It may be possible in future versions
>of bgacc; it depends on how ambitious I'm feeling :-).

Please at least feel like either:

a) ask the user for a commandline if program is named *.TTP
b) ask for commandline if user says so in the fileselector box
c) provide full CLI access from bgacc (no fancy shell features, just a CLI)

d) all three of these :)

Frankly I am surprised that (a) is not done already. It is so obvious, and
cannot be very complicated.

On a related subject, since *.TTP is conceptually different from *.PRG
in terms of user interaction from the desktop, I think the behaviour in
the new Atari desktop is wrong when a file is (some files are) dropped
into a *.TTP icon and get treated just as if they had been dropped into a
*.PRG). Instead of simply sending the filename(s) as an argument list, the
argument list should be built as normal and presented to the user for editing
and then [OK] or [cancel].

1822. I was wrong Neodesk 3 and MiNT .94 don't work together

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-07 03:02:38 UTC
From: dstailey@leidecker.gsfc.nasa.gov
Message-ID: <DSTAILEY.92May6220238@leidecker.gsfc.nasa.gov>
Source record: 44522

Recently I posted that I had experienced no imcompatibilities between
Neodes 3 and MiNT. This is only true up through MiNT .93. Yesterday,
I tried to test the new BGACC under Neodesk, and found that Neodesk simply
would not start. I tried several ways of starting neoload.prg, and they
all seemed to work. But when I started GEM, Neodesk wouldn't run at all.
It wouldn't autoload (using TOS 1.4's ability to autoload a GEM prg), and
I couldn't start it manually, either. I tried removing all TSRs and DAs,
starting neoload from /auto and from a MiNT CLI, and starting everything
from mint.cnf. Nothing worked. Neodesk did not display any error messages,
it just tried to start, and then immediately returned to the standard desktop.

Has anyone had any luck with the Neodesk/MiNT .94 combination?

1823. Sozobon and address calculations

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-07 04:05:15 UTC
From: ntomczak@vega.math.ualberta.ca
Message-ID: <ntomczak.705211515@vega>
Source record: 44523

Ian recently explained how Sozobon generates code for an array access
and why using optimizer is a good idea. Actually the situation is
much worse than that. No amount of fiddling with libraries can really
rectify the situation and will likely only create a big confusion and
incompatible workarounds. My advice - don't do that!

To explain why it is so here is a commented fragment of a assembler
code generated with -O option by Sozobon 2.0. You will get the same
results with 1.2. I do not know how this will look like with 1.33 but
I strongly suspect the same.

This code copies a contents of some cells of a global array of ints to
a similar automatic one.

```
....
move.w d3,d0 ; d3 holds an array index, copy it to scratch
asl.w #1,d0 ; compiler know that int is 2 bytes wide
ext.l d0 ; extend it to long
add.l #_arry,d0 ; add result to an address of array base
move.l d0,a0 ; store computed address
move.w d3,d0 ; repeat offset computation once again
asl.w #1,d0
ext.l d0 ; our target starts at -60(a6)
move.w (a0),-60(a6,d0.l) ; move integer to target
addq.w #1,d3 ; increment loop index
bra L3 ; do that again
```

A killer here is, of course, "asl.w #1,d0" statement. The constant
will be #2 if you are dealing with array of longs, or #3 if you will
do that for arrays of structs each containg two longs (yes, Sozobon 2.0
is smart enough to handle that) and so on. Depending on a size
of your arrays you may lose significant bits from your indices
or aquire an extra sign or both. Following "ext.l" will be not removed
by an optimizer since the previous instruction is not a multiplication.
Anyway removing it would not help at all. With ranges big enough
Boom!!! - extremely likely.

The most hilarious result you will see when your target was malloc'ed
and you overwrote book-keeping information which resides in memory
just below it. Think about it! This is really easy to do. And you
will bomb out not here but possibly far down into you program when you
will try next malloc or you will try to free your target memory.

Some three years ago I had a lengthy e-mail exchange with Sozobon
authors in which I tried to convince them that this is a bug and
they were stubbornly claiming that this is "a feature". This despite

of examples (you may easily produce them yourself) of situations
when (&array[i] + 1 == &array[i + 1]) evaluates to false. I am sorry
to say but the latest qualifies Sozobon C, despite of all its virtues,
only as a compiler of a C-like language and not of C itself. After
my failure I limited my use of Sozobon only to those unfrequent
situations when I was really sure that the problem above will not
kill me (a possible work-around is to use only unsigned longs as
you array indices but this is not always practical). I looked
at the compiler code itself but I was much less patient than Ian
and resigned in significantly shorter time than two years. :-)
You have been warned!!!

(Before misunderstandings will arise. All versions of szadb, including
those modified where I had my substantial share, were compiled with
Sozobon. But one has to tread very lightly... :-). And of course
you are perfectly OK if your program and data are small enough to
never wander into a danger zone.)

Message-ID: <ADRIAN.92May7105145@duncan.robots.ox.ac.uk>
Source record: 44525

In article <1992May06.193741.12838@infoserver.th-darmstadt.de>
wallmann@backus.pu.informatik.th-darmstadt.de (Natuerlich!) writes:

And for a little inheritance you could go like this:

```
typedef struct _method
{
struct _method *next;
int (*func)();
} method;

WINDOW *p;
method *q;
...
p->draw = inherit( p->draw, newfunc); /* *1* */
...
for( q = p->draw; q; q = q->next) /* to actually redraw */
(*q->func)( p);
```

However, it would be nice for a function to be able to choose how to call the base class functions, and to be able to react to the return values. This scheme throws away the int return values from each method call and calls each function with identical parameters. By the time you've implemented this sort of scheme you might as well go the whole way and use C++, which will do a lot more and cover up more of the messy details.

Source record: 44526
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hello Networking world,

I have the following problem:
I am having a "big" ST(2.5MB mem, 130 MB Harddisk) and a "small" one (floppy only)
just a few rooms away.
Now i am willing to connect these two computers, so the "small" one can
use the Harddisk resources of his "big" brother.
It should work from the Desktop (as am installed extra drive),
use a cheap way of connection (Midi/RS232/Centronics?), and
It`s not dead_or_alive necessary that i can work with the "big" ST while
the "small" one is accsssing files.

Does anybody know if such a thing already exists, especially if it is
Share/Freeware and/or where to get it by ftp ??

Thax in adv.

Frank

It does on my TT which I got quite some time ago. Additionally, the Monochrome monitor for the TT is much larger than the Color Monitor and I believe the recommendation is to not put the Mono Monitor on top of the computer. The local computer store has their Mono Monitor on top of a stand which sits above the TT.

Cheers!
Chuck

This is correct.. it looks ok on top of the TT too.. though I would have liked a FST type monitor with the guns aligned properly :-).

It would also have been nice if the monitor could have handled the high-res mode too, but I'm sure this was just too much to ask.

BGACC was always intended to be just a way to run a CLI. That's why it
doesn't have "built in CLI access"; you choose the CLI you want, you run
it, and then you use it to run other programs.

> Frankly I am surprised that (a) is not done already. It is so obvious, and
> cannot be very complicated.

No, it's probably not very complicated. But implementing it takes time,
and time is probably the commodity that I'm shortest of these days (with
money running a close second) :-(.

1831. Re: TOS upgrade 1.0 -> 1.4: Is it worth it ?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-07 14:50:25 UTC
From: aq115@cleveland.Freenet.Edu
Message-ID: <1992May7.145025.6337@usenet.ins.cwru.edu>
Source record: 44531

If you can get the upgrade at a good price, GET IT. There are a lot of features in TOS 1.4 that are not in 1.0. First, you can get rid of FATSPEED, and you can use a high speed modem with TOS 1.4. You can't on 1.0, because flow control is screwed up beyond any recognition. The TOS14FIX package has a few minor fixes for it.

Other than that, you might want to instead consider the TOS 2.06 upgrade from the Codeheads (TEC Board). It's not cheap, at $150, but it has even more neat features, even when using Neodesk (like I do).

I've only just discovered the ftp site atari.archive.umich.edu and discovered that C compilers are available for down-loading. My problem is I operate from a University account. I am able to transfer files to disk in an ST disk format however I don't have hands-on access to an ST machine itself. (I'm doing this for my brother who has an STe)

So currently I have copied over sozo133i.zoo and zoo21.ttp . Not having access to an ST means I can't try out the programs before I pass on the disk. I need someone to instruct me on how to dearchive sozo133i.zoo. Is the file zoo21.ttp the one I need and do I need any other files in addition to this?

1834. Ideas for an RPG 3D Dungeon

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-07 16:23:50 UTC
From: cstdxer@warwick.ac.uk
Message-ID: <62rjbvaj@csv.warwick.ac.uk>
Source record: 44534
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Ok, does only one person out there read the news? If not is there much point in posting news when only one person can be bothered to reply?
My thanks to Stefan Schoene who actually bothered to reply!
Since I'm a generous chap and not really all that nasty I'll ask again, this time filling in a few of the details, in the sincere hope that I get a little help from fellow STers!

A friend and I are in the process of writting an RPG "type" dungeon game, along the lines of Dungeon Master. We already have a fast effective graphics engine for the maze production. The main code is being written in STOS since I can see no reason (even speed!) to resort to assembly language! The initial version (we hope) will be for 1meg only. (If we get enough response) We will then squish it down for 1/2 Meg.

We will, hopefully, release an initial PD demo, with a shareware upgrade.

Questions:

Does anyone Have ANY ideas at all about how we could improve upon Dungeon Master and It's Ilke.

Do you have any suggestions as to how much, and whether, you, joe public would be willing to pay for a reasonable game, with documentation and possibly the maze designer?

Does Any one Know anything about HBL interupts? I now have a routine which almost works. It sets up the interupts but crashes. It then recovers and allows normal operation to resume. However, a) it crashes, b) there is a seriously bad flicker on the left side, c) it judders every time the mouse is moved (we need the mouse), d) it wont work within STOS. ANY help would be very appreciated!

Stefan raised one important point in his letter to me, this is that HBL rasters wont work on a TT/Mega STE. I assume he knows what he is talking about, so is there a way around this problem?

Please Please Please do reply to this letter, the more viable ideas we get the better the game can be. Help us to make this a game worth playing not just "...another Dungeon Master clone..."!

If you do reply please could you mail me at

cstdxer@csv.warwick.ac.uk

or if you'ld rather, use Pnews to reply via the news group.

Thank you in advance,

Chris

...

I ran into this problem while porting GOFER to the ST.
(See also: comp.lang.functional)
I had a short look at the sources of hcc, but I gave up quick and wrote a
post processor to apply to the assembly file.
It turns the above code into

move.w d3,d0 ; d3 holds an array index, copy it to scratch
ext.l d0 ; extend it to long
asl.l #1,d0 ; compiler know that int is 2 bytes wide
add.l #_arry,d0 ; add result to an address of array base
move.l d0,a0 ; store computed address

except that in the case of a shift of 1 the following code is faster:
```

```
move.w d3,a0 ; this is a move + extend
add.l a0,a0 ; add is faster then asl
add.l #_arry,a0
```

If anyone is interested, drop me a note and I will post the sources for the post processor.

With a Hard Drive 1.4 will probably double the access speed to directories and files. The FASTLOAD bit speeds up the loading of programs, but not by that much.

>
> I use NEODESK3. Do you think that a TOS upgrade is really worth it ?

Definitely, I went from 1.2 to 1.4 on my old 2.5Mb 520STM and will NEVER go back again.

1839. GCR trouble

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-07 19:01:12 UTC
From: ens@ccu.umanitoba.ca
Message-ID: <1992May7.190112.21630@ccu.umanitoba.ca>
Source record: 44539
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

My GCR has stopped working: After the smiling Mac, the screen clears to black and then I get the crossed out floppy. This happens whether I boot from hard disk or from a bootable (tested in a real Mac) floppy. If anyone has had similar problems, I would appreciate advice. (Gadgets' phone is always busy and a fax failed to get a response.)

Werner

1840. MegaSte: Blitter,cache,& speed

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-07 23:30:04 UTC
From: marshall@cs.uq.oz.au
Message-ID: <7820@uqcspe.cs.uq.oz.au>
Source record: 44540

I would like to turn of the blitter and cache, and set speed to 8Mhz, on my Mega4Ste, from the autofolder, so that I can boot directly to ATSpeed (I use Superboot to config. my boot settings). Is there a program to do this, or can anyone supply sources in C or Modula2? Thanks.

From: michael@dime.cs.umass.edu
Message-ID: <47496@dime.cs.umass.edu>
Source record: 44341

A couple of people have mentioned having problems running
MiNT 0.94 together with NeoDesk 3. I am successfully using MiNT 0.94
and NeoDesk 3.02 together. My machine is a Mega 2 with 4 megs and
TOS 1.2. What works for me is to put neoload and startgem before
mint in the auto folder, and then in startgem.inf list the path to
the executable neodesk.exe, NOT neoload.prg.
I don't know if it will work for any configuration other than my
own; try it at your own risk.

Look on atari.archives in the utilities directory(I think), for a file called speed_sw (arc, lzh, zoo? dunno). It contains four programs and assemble source for setting modes on a Mega STE.

The way you're supposed to run Neodesk with MiNT (as I've been told)
is to setup MINTSHEL as your autorun program, and place at the end
of the MINTSHEL.RC file:

cd \NEO3 Or whatever you call your Neodesk folder
NEOLOAD.PRG

That should do it, I think. I might be missing something, but I
don't think so.

> sozobon (all versions) problems with indexing into arrays >64k

I can understand why the Sozobon guys might have argued with you, especially with your beligerent-sounding statement "...a compiler of a C-like language and not C itself." You should say *nice* things to creators of free software, whenever possible. ::grin::

In the strictest sense, Tony & Co. were right: in a 16-bit compiler, where sizeof(int)==2, the way it is doing address calculations is technically correct.

However, I agree with you, that this is more of a bug than a feature. I spent about 3 hours yesterday trying to track down the right place in HCC to fix this whole index problem. Once again, I failed to find the critical point in the code. ::sigh::

Now I'm thinking it would be easier for me to fix the problem with the asl/ext sequence in the optimizer, by just swapping it to ext/asl.

Also, there is another workaround available: use long datatypes for indexing. It's been a while since I checked, but using a variable declared as long, or a long constant (eg, 1000000L) will always give the right results. (Maybe it's time for me to double-check that, though, before I go spouting off about it here.)

Yes. FAT handling is speeded up beyond all recognition. You'll really feel the difference with your hard drive, and you won't have the 40 folder problem anymore either.

There are a few bugs, but the general improvement far outweighs them. You can also get patch programs to remove them: POOLFIX3, TOS14FIX, and TURBOCTS.

I've never regretted upgrading from TOS 1.2

1848. GCC21 Includes Problem

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-08 15:24:30 UTC
From: malay@sae.com
Message-ID: <1992May8.152430.22524@sae.com>
Source record: 44348

I got a hold of the new "includes" and "libs" for gcc21 (gpincl07.zoo and gplibo07.zoo) and tried compiling:

```
#include <stream.h>

int
main (void)
{
cout << "Hello World\n";
return 0;
}
```

by calling gcc thusly:

```
gcc -v hello.cc -o hello.ttp -lg++
```

and I get these warnings:

```
c:\include\g++-inc\streambu.h: In method `int streambuf::sbumpc ()':
In file included from c:\include\g++-inc\iostream.h:25,
from c:\include\g++-inc\stream.h:7, from hello.cc:1:
c:\include\g++-inc\streambu.h:317:warning unknown escape sequence '\i'
c:\include\g++-inc\streambu.h:317:warning unknown escape sequence '\g'
c:\include\g++-inc\streambu.h:317:warning unknown escape sequence '\s'
c:\include\g++-inc\streambu.h: In method `int streambuf::sgetc()':
c:\include\g++-inc\streambu.h:331:warning unknown escape sequence '\i'
c:\include\g++-inc\streambu.h:331:warning unknown escape sequence '\g'
c:\include\g++-inc\streambu.h:331:warning unknown escape sequence '\s'
c:\include\g++-inc\streambu.h: In method `int streambuf::snextc()':
c:\include\g++-inc\streambu.h:344:warning unknown escape sequence '\i'
c:\include\g++-inc\streambu.h:344:warning unknown escape sequence '\g'
c:\include\g++-inc\streambu.h:344:warning unknown escape sequence '\s'
c:\include\g++-inc\streambu.h: In method `int streambuf::sputc()':
c:\include\g++-inc\streambu.h:374:warning unknown escape sequence '\i'
c:\include\g++-inc\streambu.h:374:warning unknown escape sequence '\g'
c:\include\g++-inc\streambu.h:374:warning unknown escape sequence '\s'
```

the program links successfully and runs fine. I peeked at the "streambu.h" file and examined the offending lines and they appear in a :
#ifndef atarist - #endif
bracket - why is the compiler complaining about code that it should not be looking at? "atarist" is defined because a "-Datarist" appears in the call to gcc-cc1.ttp. Any clues?

I don't know about the article you mentioned, but if anyone has C code
for Bezier Curves, I could optimize into assembly by hand and share it
with everyone.

Also if anyone does find the article mentioned, I too would be interested.

Hello out there !
I'm looking for the Sources, that implement the so called 'JPEG' algorithm.
As far as i know, it is mainly used for compressing Images.
Does anyone know where i could get them, or who wrote the Software ?

greetings Theo

Perhaps some German friends will correct me but there was an article
in the Feburary issue (1992) of ST Computer (the German magazine) with
the title 'Fast Bezier curves' pages 80 to 82 - in German of course.
The article contained a listing of a 68000 assembler program which presumably
did the job.

i have some code, tho it writes the "curve" directly to screen memory. i
believe it is bresheman's (sp?) algorithm. i use it in a home-grown (manual)
screen saver. i did not write the bez stuff. it is C. i can post it (don't
have time to mail to 1000 people). actually, i thought i did post it a long
time ago. i think the code was originally written for a PC and i hacked it.
GEM purists will of course hate it since it writes to screen memory... :-)

another source might be the source for DWB pic(1) which has a spline function.
i thought i remembered this being bez curves. i have the pic source, but it
is (c) AT&T so i can't distribute it. it probably also depends on troff.

if erik@microware.com wants the code, i can mail it to you (send me mail).

Hi,

I am trying to use Sversion() to get the TOS number from rom.

I have TOS 1.4 in my 1040 ST however I get a result returned from the function:

highbyte = $15
lowbyte = $00

According to the documentation with Laser 'C' The high byte is the version
number and the low byte is the point number.

But it is not sending me that!

Why? Any ideas? Anyone done the same thing?

I have re-written the format routine and need to know the TOS number so I can
allow for the different locations of low memory between TOS's.

Any clues would be appreciated.

Thanks,

<><><>

If you're running a hard drive then TOS 1.4 is considerably faster than
the earlier implementations for disk accesses. The bug fixes are mostly
concerned with the RS232 port (get TOS14FX2.PRG) and the memory pool
(POOLFIX3.PRG). I also use the good old FOLDERXXX.PRG because that bug
can still bite, although very rarely and a lot less terminally. I
still use Pinhead but that's largely laziness because that works on all
my programs without my having to go through the entire hard drive.

I changed up from 1.2 and it was well worth the trouble.

May I ask you how did you reach that conclusion? I heard it
occasionaly but it always due to a mixup on a reader part between
"integer type" and "int". If you read K&R more carefuly (I just found
to my great dismay that my copy of the first edition evaporated
somewhere so I cannot quote) you will find out that these two
are not necessarily the same. Apart of that with the interpretation
like above the pointer arithmetics breaks horribly. The last one
happens to be one of better specified parts of K&R and this is a reason
I used an expression of "a C-like language".

> However, I agree with you, that this is more of a bug than a feature.
> Now I'm thinking it would be easier for me to fix the problem with the
>asl/ext sequence in the optimizer, by just swapping it to ext/asl.
>
This has an unfortunate effect of making an optimized and unoptimized
code non-equivalent :-(. And there is one more "gotcha". If you
are using unsigned indices then a correct sequence to generate
would be:
```
moveq #0,dn
move dm,dn
asl #k,dn
```
or something similar. Compiler should know that but optimizer,
working on assembler code without an info about types, does not.

> Also, there is another workaround available: use long datatypes for
>indexing.
This works and I even mentioned that in my original article. The
problem is when you are not writing your code (carefuly) from scratch
but when you are porting sizeable piece of code from somewhere else.

Changing in blind all types for array indices can have unexpected
side effects. I would rather postprocess a generated assembler. :-)
For the first cut a simple awk program will do. (The other possibility
is to add casts to every variable occurence in a role of an array
index - shudder...).

Do you perhaps mean the difference between "integral type" and "int"?
The expression E1[E2] is identical to *(E1 + E2*sizeof(*E1)). I can't
find any rule that says that E2*sizeof(*E1) has to yield a result wider
than the type of E1 or E2. In other words, if size_t is unsigned short
int, and E2 is a short or unsigned short int, then I can't find where
it says that the results have to be promoted to a size larger than
unsigned short int.

> optimized and non-optimized code not equivalent

Well, I have good news, bad news, and a question for everyone. The
good news is, I FINALLY FIXED IT!!! Yaaaay!

The bad news is, it now considers all address calculations to be
something that requires long math. For indexing into arrays with a
power-of-two element size, this is no big deal; you get code such as:

move.w index,d0
ext.l d0
asl.l #2,d0

But when you have an array of structures that are 12 bytes each, you get:

move.w index,d0
ext.l d0
move.l d0,-(sp)
move.l #12,-(sp)
jsr lmul

Even though the lmul routine is fast in sozobon/hsc, this is really not
ideal, and in some situations will be a serious performance problem.
(Especially in GEM programming where arrays of structures are common.)

By the way, I should clarify: I fixed it in HCC, not in TOP, so it
correctly handles signed versus unsigned index calcs, and so on.

My question is: should I implement a new command line switch to toggle
this behavior? I'm thinking that if you never deal with arrays of
objects that exceed 64k in size, you can get a serious performance boost
by using short address calcs. If in doubt, or if you know you'll be
using large arrays, a switch will kick in the long address calcs.
In the MSDOS world, this is roughly equivalent to the difference between
large model and huge model, so I'm tempted to make a new -mX switch,
where 'X' is the model you want; 'h' for huge model (address calcs
```

assume object can be over 64k), 'l' for large model (what it does now;
program and data can be any size, but no single object is >64k), and
someday in the future I may do a small model for when your total data
size is under 64k and all data objects can be addressed off a base reg.

What I don't want to do, at least not yet, is introduce model semantics
into pointer declarations (ie, char huge *ptr, and so on). The whole
type declaration parsing subsystem would have to be recoded to handle
that, and it's gonna get recoded when it comes time to support prototypes
properly, so maybe then I'll consider model semantics in declarations.

So, would everyone be happy with long/short address calcs toggled by
a command line switch, for now? The default would pretty much have to
be -ml (short addr calcs) for compatibility with existing code.

- Ian

Message-ID: <1992May9.231956.4754@kosmos.wcc.govt.nz>
Source record: 44359

Does any one know the answer to this..

I have managed to get this site to implement Zmodem, this is
the Vax/VMS version that is on A.A. 1988..

I am using the GRZSZ19B program, but I only get 512 blocks
when I use this on this site..

How can I set the block size to 1024 bytes..

I have had the same problem with a Unix site, but a Atari chap used
a PC on the same site but gets 1024 byte blocks, so how come.. ??

Is this because we are not using Auto Zmodem, ie, to much delay in
setting RZ up, so that it drops down to 512 byte blocks..??

Any ideas any one..??

Sversion returns the GEMDOS version, not the TOS version. u get TOS from the OS header. so there are at least 3 pieces of the OS with versions: TOS (use OS header), GEMDOS (use Sversion), and AES (in one of the control arrays after an appl_init). 0x1500 sounds reasonable for GEMDOS under TOS 1.4 (Rainbow).

Give this guy in Tampa a call, he can set you up. His store name is A-online, ask for Allen, tell him Dave sent you. 237-1656, 1229 Mohawk Ave. 10blks east of 275 overpass staying on Hillsbourgh Ave, behind Cottman on left,turn left, A-online on left! He is the only Tampa Bay store, prices are okay. Main thing is no wait on mail order. He also supports the 8 bit, someSTe's on display.. check him out! I bought my 520STe w/4 megs there for $525, not a bad price! Stero monitor was $350.. Well worth

the investment ithink.. Although, i would love too get a new Mega STe, he has one on display,great keyboard, nice style. $1199.95 with 50 meg HD, 4 megs of RAM i think.. Good luck!

C is a programming language. Not ROM code. There is no problem changing
this into accepting the return value and doing stuff with it.

if( q = p->draw) /* this if could be dropped... */
if( (*q->func)( p, q->next)) /* let q->func call q->next->func */
do_stuff();

No sweat.
But actually that's beside the point. I was just intending to show that
you could do some inheritance-like stuff in C easily, which is quite handy
for instance if you have a default slider routine for calculating the
size of the slider, and putting a routine on top of it, that's more
application dependent.

>time you've implemented this sort of scheme you might as well go the
>whole way and use C++, which will do a lot more and cover up more of
>the messy details.
Oh no. I implemented this scheme in just about 2 minutes. It would take
me months to understand C++. (Let alone that I don't see a C++ compiler
```

around, that I'd like to use).
>
>- Adrian

Nat!

P.S. From this included post of mine, I think I might have forgotten
to 'code' inherit, here it comes:

```
method *method_allocer() /* a la NASM65 (for the insiders) */

#define inherit( p, q) \
(tmp = method_allocer(), tmp->next = p, tmp->func = q; tmp)
```

P.P.S. just wonder whether you can do it in FORTRAN too (har har)

Well, I wrote a program in Turbo Pascal (under MuSh-DOS), but I imagine I could convert it to 68000 assembly for you... If I find the time. It's really not very difficult. All I have to do is get around the fact that I am doing no floating-point computations.... something I do quite frequently.

Pardon me, but why are all of you so interested in FINDING already written bezier curve producing code? Bezier curves are not all that difficult mathematically, and equally easy to program from scratch. Why don't you? I would be happy, though, to supply you with Pascal source code that draws bezier curves quite well, and perhapse I might be talked into converting it to assembly for you.

I would be interested in that myself, but I would be EVEN MORE interested in getting my finger-tips on some code that preforms Fractal image compression and decompression. I have been reading books to learn about Fractals, but it is a difficult and slow process, and I doubt I would be able to derive the formulas on my own that would preform the necessary iterative computations to preform fractal image compression.

I seem to have missed some of the conversation, but are you writing a C compiler?

I would not mind it the least bit if the compiler was just a bit slower, if it figured out intelligently, on its own, which individual arrays and the like should be addressed as large or huge, thus completely illiminating the need for explicitly specifying the addressing mode. Quite a number of compilers for the ST to that already.

1868. An ACSI/SCSI problem

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-11 07:46:43 UTC
From: gertjan@kompas.prl.philips.nl
Message-ID: <5527@prles2.prl.philips.nl>
Source record: 44362

A ACSI - SCSI problem:

I have built a SCSI host adapter for my atari ST and it doesn't work well.
The schematics I used were the ones suggested by the Atari Corp. and I checked
everything with a logic analizer. The harddisk I use is a Quantum LPS52S.

What goes wrong is: the harddisk becomes selected and reads the six command
bytes. But he never gets into the data phase, and goes directly into the status
and message phase (returns status 2). So as far as I can see is the ACSI and
SCSI protocol handled in a good way, but my harddisk doesnt understand the
commands. I used the commands: test drive ready, request sense and read block.
The harddisk works on other computers very well.

What am I doing wrong?? I think I overlook something very obvious.
Please answer me by email: gertjan@prl.philips.nl

Thanks in advance!

The reference is OK. I have the magazine in front of me. The code is
quite short. But I am afraid my typing speed is not so great and I might
make mistakes. I hope we will get soon an OCR here at work so that will
solve the problem, but perhaps someone else can post the article?

It uses integer math and there seems to be interface to Turbo C.

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-11 20:01:51 UTC
From: vspicer@ccu.umanitoba.ca
Message-ID: <1992May11.200151.29635@ccu.umanitoba.ca>
Source record: 44366

hello world. we need an assembler which can handle op-codes for 68010-68030
in order to tinker with some DMA SCSI driving in assembly code.
can anyone suggest a good assembler (commercial or otherwise), and
how/where to find it?

we've tried the "as68" development assembler, it complains about
addressing modes and 68010 opcodes. the GNU assembler that comes with
GCC is nice, but non-standard in how it handles the op-codes, and it
doesn't support EQUates or macros.

thanks in advance
vic spicer

I have the article here - it was in the german 'ST-Magazin' 11/1989. There are
listings in Assembler (211 lines), C (90 lines) and Omikron-Basic (60 Lines) -
but all these are too long to type in at the moment.

Sversion() returns the GEMDOS version number, *not* the TOS version number.

The files at a.a.u.e seem to be the ancient and buggy version-1 release of
the Independent JPEG Group's software. You DON'T want that version.
What you DO want is version 3, which is available from the IJG's official
archive site, ftp.uu.net, file /graphics/jpeg/jpegsrc.v3.tar.Z.

If you have no FTP access, you can retrieve the source from your nearest
comp.sources.misc archive; version 3 appeared as issues 1-18 of volume 29.
(See the "How to find sources" FAQ article, which appears regularly in
news.answers, if you don't know how to retrieve comp.sources.misc postings.)

If anyone knows the a.a.u.e archive maintainer, please ask him/her to flush
v1 and install v3 instead.

v3 is faster, less buggy and more portable than v1; it has a MUCH better
color quantizer for GIF output; and it supports Targa image file format as
well as GIF and PPM. I'd really like to see all copies of v1 stamped out...
not to mention the pre-v1 beta releases that somehow got out on the net.

After running certain programs on my Mega4Ste, I get a wrap-around ghost image,
on the left, of what should be on the right, of the screen.
I think this problem has been noted before. What was the solution? Thanks.

From: marshall@cs.uq.oz.au
Message-ID: <7882@uqcspe.cs.uq.oz.au>
Source record: 44377

I am running ATSpeed with EGA mono emulation, on my Mega4Ste and SM124 mono monitor. All my PC programs work fine,
EXCEPT for DRDos's Viewmax. The screen comes up as expected, but the icon labels are very hard to read, and when I try to pull down a menu, the menu is blotted out with a dense grey pattern. Viewmax runs OK when I emulate CGA. Also, Viewmax works fine on my real 386 with VGA colour.
So what is going wrong? Any help would be greatly appreciated.

> are you writing a compiler

Not exactly; just doing major maintenance on my offshoot version of the Sozobon PD compiler. (Although at the rate I'm going lately, I'll feel justified in calling it 'mine' soon; I've been making some pretty basic changes lately.)

> figure out on its own which arrays need to be large or huge...

That's possible (not easy, but possible) for pointers to array defined in the program. It's not possible with dynamically allocated arrays, though, unless you get into the char huge *ptr sort of thing where the size semantics are in the declaration.

I did manage to fix the code generator so that it indexes properly into large arrays, as long the object size of one array element is under 64k in size. I even managed to get the right codegen without needing long multiplies or memory model switches.

It has been pointed out to me, via some email discussions, that the compiler is broken in that it lets you allocate arrays larger than size_t can express. Technically, I should have the compiler whine and die if you define an array larger than 64k, because sizeof(such_an_array) will give the wrong results. For now, I choose to view this 'feature' as a non-standard extension in the compiler, as follows: you can allocate arrays larger than 64k, and you can successfully access all array elements using normal int/size_t index expressions, providing that the size of one array element doesn't exceed 64k. You cannot use sizeof() on such an array. If the size of one array element does exceed 64k (not likely), you can still access the full array by using long-type index expressions.

For the record, language lawyers (reliable ones, that were on the X3J11) committee) have assured me that the compiler is *not* broken because of having size_t be unsigned short even though the chip and OS can support access to larger objects. It is broken only in that it doesn't whine when you define arrays larger than 64k.

1881. Re: TOS upgrade 1.0 -> 1.4: Is it worth it ?

> No manual or anything came with the upgrade (from Evesham Micros) apart
> from when I rang in the order, they told me where to put the chips when
> I get them. Could someone tell me what TOS 1.4 does the 1.0 didn't....

Well, this is from memory - I did the upgrade a few months ago.

1) FAT handling is much better, particularly on a hard disk. With TOS 1.0, a "Show Info..." on each of my hard disk partitions took about 16 seconds. With TOS 1.4 in, it takes about 2-3 seconds.

2) You no longer run out of folders in the same way 1.0 did. I often used to hit it with prolonged usage under 1.0. I have never hit it under 1.4.

3) Whole disk copying and Format now use the same dialogue box, allowing Formatting and Copying to be done alternately if required, without having to keep going back to the desktop.

4) If you hold the CONTROL key down while dragging a file, it will MOVE the file instead of COPY it. If the source and destination are within the same logical drive, I believe it just moves the directory entry of the file, leaving the data in place on the disk. If the source and destination are different drives, it copies the file and deletes the original. If you MOVE a directory, it appears to create a new directory, and then move each file in turn, and finally delete the old directory.

5) You can install a GEM application to auto-run from boot.

6) Install application now stores the complete pathname of the installed application program, allowing it to be used on files in any directory.

7) In colour modes, the Atari-logo in the desktop info dialogue box changes colour in a rainbow pattern (Wow! :-)

8) You can rename a directory (folder), using Show Info...

9) When copying, moving or deleting files, the dialogue box shows the directory and file being acted upon, instead of just a countdown.

10) The file selector dialogue box contains drive buttons for easily switching between logical drives without having to edit the file spec.

Any others I have missed?

Tony.

Hello...

There is a very good and fast assembler included in the german
PureC (TurboC) development kit. It also assembles 68000 as 68010
68020, 68030 and (!) 68040 codes.

The Shell and the usage is very good, fast and easy.

The price in germany is 350DM, I'm sure that it is possible for
you to get one in your country.

Roland.

I doubt it is worth buying a C compiler just for the assembler, but if you were going to buy a C compiler anyway, the Lattice C5 one handles 68000-030 opcodes, and the documentation is available in English. In England it costs STG150.
The best standalone assembler is meant to be Devpac ST V3, but it is considerably overpriced (I forget the exact amount).
Both of these are from Hisoft, who incidentally offer discounts to full-time students.

performing the proper formatting if they are configured correctly.)

Ian Lepore is author of Heat and Serve C, a modified descendant of
Sozobon C. The original was written by Hans Ruegg, Joe Treat and Tony
Andrews.

> > I would not mind it the least bit if the compiler was just a bit
slower, if it figured out intelligently, on its own, which individual
arrays and the like should be addressed as large or huge, thus
completely illiminating the need for explicitly specifying the
addressing mode. Quite a number of compilers for the ST to that
already.

If that's possible, I wouldn't mind if the compiler were slowed down
a little bit while trying to figure out whether it would be necessary
to call lmul().

But I would mind a whole lot if it generated slower code
unnecessarily. My Usenet software would suffer a significant
performance hit if it had to call a library function to compute
addresses offset from a roving pointer. For example:

```
} else if((groups == NULL)
&& ((p == buf) || (p[-1] == '\n'))
&& ((p[0] == 'N') || (p[0] == 'n'))
&& ((p[1] == 'e') || (p[1] == 'E'))
&& ((p[2] == 'w') || (p[2] == 'W'))
&& ((p[3] == 's') || (p[3] == 'S'))
&& ((p[4] == 'g') || (p[4] == 'G'))
&& ((p[5] == 'r') || (p[5] == 'R'))
&& ((p[6] == 'o') || (p[6] == 'O'))
&& ((p[7] == 'u') || (p[7] == 'U'))
&& ((p[8] == 'p') || (p[8] == 'P'))
&& ((p[9] == 's') || (p[9] == 'S'))
&& (p[10] == ':')) {
```

The whole point of unrolling a string search like this is to push performance to the limits. If I didn't care about performance, I'd call strnicmp and have much simpler code.

Ian's suggestion of a compiler flag seems reasonable to me. As I understand it, you would be able to isolate a module that needs to address huge arrays and compile it separately. You wouldn't have the memory-module incompatibility problems that plague PC folks.

I am not a MiNT user, but I am a NeoDesk user (or abuser as the case may be).
Have you tried running Neoload.prg from the auto folder before other apps?

I read in the NeoDesk manual that in order to ensure that NeoDesk will be
exacutable from within another program, this should be done. According to
the manual, there is no memory penalty from running neoload twice and it
might solve your problem. Maybe?

Devpak3 from HiSoft supports 680x0 chips (where x is 0,1,2 or 3), maths coprocessors (however they're connected) and all the enhancements that the TT has.

As well as all this, it's a first-class assembler, with macros, conditional assembly etc. etc. and a full debugger.

I believe that Goldleaf Publishing distributes HiSoft stuff in the US -- I'm sure someone will correct me if I'm wrong and provide an address otherwise.

In general, there is (on the Atari) no way to find the name of your program (I mean, no way that is *guaranteed* to work). The method you mention indeed seems to be the most straightforward - although, admitted, not too elegant. It also depends on the language you use: in Basic, your method probably is the only available one. I have some Turbo-C startup-code that uses another trick (don't ask me which :) and seems to work *very* reliably in all cases (plain starting of the program, running from a shell, running through an 'install application' document, etc.)

Jump to/through :) the reset-vector: 0x00000004 on the ST. I don't know the TT address - will probably be something different, but that can easily be solved with something like

```
#ifdef ST
#define RESETVECTOR 0x4L
#else
#ifdef TT
#define RESETVECTOR 0x...L
```

Hope this helps a bit,

11) Cntl-Alt-Del (cold?/warm?) resets the machine.

12) You can use overscan programs!

13) You need to patch the RTS/CTS bug if you want to use a high-speed modem.
(well, 1.0 had this bug, but I think it was gone in 1.2, and reappeared).

Anything else????

>compilers for the ST to that already.

Nope. Unless you limit this mechanism to very simple programs, you just
cannot do this. Imagine the following function:

```
void f (int array[])
{
...

array[...] = ...
}
```

You just cannot tell if long or short addressing must be used. So you must
default to long. As far as I know you can tell the difference in FORTRAN...
Some other message stated that a compiler that uses short addressing should
complain about allocating objects greater than 64kB. I agree with this
statement, though limiting objects to 64k would be silly on a 68000 with
4 MB of RAM...

Just my two NLG 0.02...

1900. Floppies: Sun to Atari

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-13 09:50:45 UTC
From: davidb@muppet.bt.co.uk
Message-ID: <1992May13.095045.474@muppet.bt.co.uk>
Source record: 44454

Hi chaps/chappettes,

I have a Sun sparc at work and an Atari at home (lucky ol' me).

I have no trouble writing files from the Atari on to a DOS
formatted floppy at home. I can take this to work and read
those files on to the Sun.

I can also write to this same disk on the Sun. The problem
arises on the atari when I try to read files written from the
Sun on to the disk. The files are corrupted. Not garbage, but
seriously screwed up. Looks to me like block size, but I may
be wrong. I feel sure one of you guys can sort it immediately,
or point me at a FAQ with the answer.

Thank you v. much for any assistance you may be able to throw
my way.

Unless Atari were being particularly awkward (It is possible to move the exception vectors on 68010+ chips) I don't see why this would have changed. Remember to be in Supervisor mode when you jump through this address otherwise the machine will just crash.
From C do the following:

```
#include <osbind.h>
#define resvec ((void *)0x4L) /* Can't be bothered with proper cast */

{
Super(NULL); /* Enter supervisor mode */
(*resvec)(); /* Jump through reset vector */
}
```

From: cstdxas@warwick.ac.uk
Message-ID: <t61jbzcw@csv.warwick.ac.uk>
Source record: 44452

1) Is the IBM compatable disk format given by the desktop with TOS1.04 and above handled by Protobt, or is the code just in the desktop?
2) Do HD disks have double the number of sectors, or double the number of tracks? If double the number of sectors, is 20 sectors OK as an extended format? If double the number if tracks can you still use 10 sectors?
3) On what versions of TOS does Protobt handle HD disks (if any), and what is the disk type number for HD disks?
4) On what versions of TOS does Flopfmt allow you to format HD disks (if any)?

Thanks in advance, Leo Hendry

1903. Monitors for TT

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-13 11:15:41 UTC
From: hrs@aber.ac.uk
Message-ID: <1992May13.111541.14087@aber.ac.uk>
Source record: 44453

I'm sure this is an often asked question and perhaps I should have mailed to
atari.st but can I plug any old VGA monitor into the TT monitor port?
I'm getting a lot of flicker on a PCT1426 (even when not sitting on top of
the TT), the colours are washed out and there is some distortion at the top.

TOS 1.4-1.0

1. You can reaset from the key Board. ^Alt/Del = Soft reset
^Alt/Rsft/Del Cold Reset
2. Archive Bit now the same as a PC..
3. The formating is now PC compatible..
4. Copy/Delete/Move can be aborted with the Undo Key..
5. Correct time stamp of files..
6. a Skip option when copying files..
7. Install Application has a Remove option..

The Atari Notes that I have list 34 items (Changes) for the DeskTop,
8 items for the AES, 3 items for the VDI and 33, items for the BIOS.

This is from the old TOS 1.4 notes, the later was called RainBow TOS,
this list does not have the BIOS calls for step rates for drives A and B
disk drives..

1906. GEM C++ classes - ready.

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-13 14:49:37 UTC
From: warwick@cs.uq.oz.au
Message-ID: <7905@uqcspe.cs.uq.oz.au>
Source record: 44455

I finally installed GCC2.1, and 4Meg of memory, so I've been able to polish up my G++ classes for GEM. They are only the essential Object Orientations of regular GEM, but they are quite neato.

I've uploaded them the the "new" directory of atari.archive.umich.edu, but since Jeff's taking a bit of a break, you might want to grab them directly from "new" - the file is "gem++.zoo". You can't get a list of the directory, but you can still "get" from it.

I hope we can kick this stuff around a bit - GEM becomes SOOOOO easy once you OOP it up!

```
********
tgem.cc
********

#include "tgem.h"
#include "gem.h"
#include "slider.h"

GEMrsc RSC("tgem.rsc");
GEMdesktop Desktop(DESKTOP);
GEMform About(ABOUT);
GEMformwindow Tests(TESTS);

class Menu : public GEMmenu
{
ClickResult Do(int item);
};

ClickResult Menu::Do(int item)
{
switch (item) {
case DOABOUT: About.Do();
break; case OPENTEST: Tests.open();
break; case DOQUIT: return EndInteraction;
}
return ContinueInteraction;
}

Menu menu(MENU);

main()
{
Slider SimpleSlider(SIMPKNOB,SIMPSLID,Tests);
Slider VertSlider(VKNOB,VRACK,Tests);
Slider HorzSlider(HKNOB,HRACK,Tests);
```

```
GEMactivity Application(menu,Desktop);
Application.AddWindow(Tests);
Application.Do();
}
```

```

Your floppy might be out of alignment. I know mine is (again)
so I can no longer read and write ST disks to the SUN. If some
of the files can be read and then others are corrupt, that
might be your problem.

What are you using to read/write the disks on the SUN? Mtools?

Mike Healy

1910. Lattice C and others

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-13 18:01:25 UTC
From: ens@ccu.umanitoba.ca
Message-ID: <1992May13.180125.628@ccu.umanitoba.ca>
Source record: 44460

We are using LaserC for development on a TT simply because we had it from an old ST. However we have been advised to move to a better development package and recently the need to assemble and link to a foreign package has made it imperitive. From the advice Atari gave me Lattice C from HiSoft is the pkg of choice but I am confused about a few things.

1. I gather Lattice C contains an assembler but it is not as complete as the assembler that comes with devpak TT (also from HiSoft). Does it support EQUates, or do I need to buy both the Lattice C pkg and Devpak TT?

2. I'm told Lattice does not support in-line assembler. Since I have a lot of in-line assembler in my code, it would be nice as a first step to link the foreign code with the present Laser C code. So my question is, does Lattice use the DRI object code format used by LaserC?

3. A related question is, are there any packages that do support in-line assembly?

Any alternative suggestions are welcome.

Thanks in advance
Werner

(Why is it so difficult to get information on development packages? In the good ol' days both megamax and Mark Williams had full page ads detailing their features, compile times etc.)

>I need a way, which will work on _every_ TOS-Version :)

it may be a bit rued but just load the long value at adress 4 into
the PC. Be sure to do it in Supervisor mode or you will get bombs.

typedef int (*FUNCTION)();

void doreset(void)
{
FUNCTION reset;

Super(0);
reset=*(FUNCTION *)0x4L;
reset();
}

Never tried it but it should work. Let me know by email if you tried it
with succes.

>their names? Do they just search the AUTO folder for program names
>with the right prefix, or is there something more subtle?
>
You said it already they just search the AUTO folder. It is impossible
for any AUTO prog to find out its name. Atari did adopt a protocol
that makes it possible for programs started from shell's to find out there
name but since it is not include in TOS directly it doesn't work in the
AUTO folder. This is because the calling program (the one that starts the
one that wants to know its name) must take some specific action and TOS
doesn't do that.

VAX Problems...

Well I connect to a Vax but as there is no good VT100 emulator
out for ST, and this site will only quote keys like Gold and Remove,
are there some good notes on VT100 keys codes...

Also there are some key codes that convert to Control combinations,
does any one have a list of these...Thanks..

Note: I use the TPU/EVE Editor, but the online Help does not give
the Control combination Key codes..

Second question, I did read some were there was a VT220 Emulator out
for the ST, is this Shareware or PD..

And were would I get it from... Thanks...

Roger.. sheppard_r@kosmos.wcc.govt.nz

1915. Speed change, blitter, booting etc

Thanks to everyone who responded to my request about how to change speed
from the auto folder. I use Superboot to select the required auto
configuration, and in the auto folder I have the speed_sw programs to
switch to 8Mhz. All other configs I leave at 16Mhz with cache.
Also, the same helpful person who wrote speed_sw sent me a little auto
program to turn of the blitter, so now I can do everything via the auto. BUT
I also have to disable the configuration CPX, or remove the control panel
ACC from the auto config. Then everything works fine. Thanks again.

> VT100 emulators and VAXen

Flash II suports VT52, 100, 101, 101, 200, and 300 emulation. A couple of the Flash II beta testers use it to connect to VAXen both locally and via modem, and report that TPU/EVE, PHONE, and other VT-intensive emulation tasks work perfectly. The emulation support includes proper handling of the keypad, builtin DEC character sets such as the graphics and international character sets, and so on.

For my own part, I've never done any really strenuous VT100 testing, but everything I have done with Flash II in VT100 mode works perfectly. I've told the mail reader on this system I'm using that I'm on a VT100, and it works fine, using underlined chars for the subject lines and things like that. I also use VT100 mode in the online chat subsystem on BIX, and that includes independant scrolling regions on the screen and whatnot.

> jumping through 0x00000004L to reset the ST, and the VBR

I seriously doubt that any ST software revectors 0x00000004 to something other than a reset routine, since a lot of programs would break. On a TT that was running a virtual machine type operating system extension (which I don't think there are any of, *yet*), it might be vector to restart the virtual machine rather than the whole system, but that would still give you the expected result.

Also, there's the fact that the ST's MMU remaps an access to the first 8 bytes of memory into the ROM address space -- that happens outside the 680x0 chip's control. But, I'm not sure the TT MMU works the same.

Has anyone managed to rebuild the MiNT librarys in a format that either LATTICE C, or better MEGAMAX LASER C could understand, as I have had no joy trying to do it myself (I think that my system is to small for the job...).

I post in hope!!!

> ------------------------------

hi,

there is one thing I don`t quite get - what do you mean that the
atari can only accept 3 charakters? If you`re talking about file-handling
then atari accepts 8 charakters!

Other than that, it would be intersting to know what tex-version you are
using (Strunk-Tex, Lindner-Tex, other ?), then it would be easier to help.
If I assume one of the first two tex-versions, then there is a prog
called initex, with wich you can create the .fmt files. It all works via
shell, which is much more comfortable.

1923. MiNT docs and MGR windows.

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-14 11:53:00 UTC
From: MORGADO@VXDESY.DESY.DE
Message-ID: <01GK05J3K4N49X3TC6@vax58b.desy.de>
Source record: 44470

First of all I'd like to thank everyone who responded to my request for help in understanding the interactive response problems I was having while running my own background jobs under MiNT. I received many useful suggestions which I am working on as I learn more about the ST, C, MiNT and life.

Anyway, in an attempt to read the documentation that comes with MiNT I dowloaded a man reader and manpager from the lancs.pdsoft archive. Superb bit of kit, BUT, although it works on some man files it does not work on the ones that come with MiNT. It seems not to understand the format commands in the files. All the man files are of the type `filename.1', so why is it complaining? A VAX/VMS person like myself concludes that there must be two man file standards. Can I convert between them, or can anyone suggest a reader for the pages that come with MiNT? Someone once told me that there is a man file to LaTeX converter in the GNU libraries, but I have yet to come accross it. This would partially solve my problem since it would allow me to make a hardcopy of the documentation.

Secondly, when I run TCSH under MiNT I can used the cursor keys to move through the history buffer. However, if I fire up TCSH from within a MGR window this VERY useful feature stops working, nothing happens when you press the keys. Is it possible to solve this problem? Is this anything to do with TERMCAP? What is a TERMCAP file??

Thanks in advance,

Carlos

>TT?

The assembler probably does everything you need it to (Including EQUates,
macros and 68000-68030 code), but doesn't have some advanced features such as
register equates. The only restriction I have ever come against is that you
cannot have labels local to a macro, which effectively means you can't have
labels in a macro if you use that macro more than once.

>
>2. I'm told Lattice does not support in-line assembler. Since I have a
>lot of in-line assembler in my code, it would be nice as a first step
>to link the foreign code with the present Laser C code. So my question
>is, does Lattice use the DRI object code format used by LaserC?

This is true, but you can insert binary values directly into the code, so for
the odd assembler instruction you can find out what it's binary equivalent is,
and use that feature. However, there shouldn't be any need to use in-line
assembler, and if you ever want to convert the code to another machine (even
just to optimise it for a 68030), it is much better to have all the assembly
seperate from the C. Also there is no guarantee that any assumptions you have
made in your inline assembly are going to be true with a different compiler,
so it probably won't work with anyway.

>to link the foreign code with the present Laser C code. So my question
>is, does Lattice use the DRI object code format used by LaserC?

No it doesn't, it uses it's own format because, according to the manual,
the DRI format does't support the structures required by Lattice C. In which
case it should be possible to write a DRI to Lattice C object code converter.
It can produce GST format though (and comes with a GST linker).

>Any alternative suggestions are welcome.

I expect you will get the usual people telling you to convert the whole lot to
GFA Basic (The makers of which haven't given away the latest versions of all

their software packages in ST Format over the last 2 months, honest).

1925. GCC & getenv

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-14 14:37:08 UTC
From: malay@sae.com
Message-ID: <1992May14.143708.1510@sae.com>
Source record: 44476

Does anybody have a subroutine that converts the value returned by a call to "getenv ("PATH")" to a path that looks "Atari-ish"?? The string I get back looks like:

/dev/c//\bin:/dev/d//\dtp\wp

I would like it to look like:

c:\bin,d:\dtp\wp

Seems easy enough - I just don't want to re-invent the wheel.

Bob Malay

1926. How do I drop the DTR so that the modem drops the connection?

Hi.

Does anyone know how to tell the computer to drop the DTR so that the modem drops the connection? This is a small feature of the new version of my terminal program, but it is an important one. Just about everything else has been re-worked in it. Anyway, any help on this would be appreciated.

Thanks.

I still don't see what your problem is. Especially with dynamically allocated arrays. A pointer is a pointer. You should be able to add any value to the location in an address register. In this case, it's the programmer's choise as to whether he adds an int, unsigned, long, or unsigned long to the pointer to access a memory location. You would use:

instr.? 0(A0, D0.?), ??

Where A0 is the pointer loaded into a temp address register and D0 is the offset, whether long or int. You have to check what the type of the variable is before you compile the instruction.

The easiest way I have found to reset the computer is to tell the operating system to switch to a screen resolution that doesn't exist, like:

```
Setscreen(Physbase(), Logbase(), 13);
```

Since 13 doesn't exist, the computer resets (or at least on tos 1.2 it does)

That's an interesting way of doing that. That's about how I do some assembly programming. I have 4 copies of a piece of code that handles the 4 ST bit planes instead of using a loop because it illiminates the need for loop control variables and instructions, freeing up more data registers for quick computations.

The trick probably is to get the parent's basepage adress, use it to locate
the parent's saved stack pointer, and use this to locate the argument passed
to Pexec, which is the current program's name. I first saw this in some old
Sozobon startup code. It's a dirty way, and fails under Mint (since Mint
does not put a parent basepage adress into your basepage).

Btw, don't use "comp" as a distribution, since this will make some mailers
just put your msg into their trash can; use "world" instead, or don't use
any Distribution at all.

Well, I *hope* it doesn't take until version 3 to get all the bugs out!
I just received the first post-2.0 beta version today (I haven't unpacked
it yet). This one is supposed to fix the worst of the 2.0 bugs, but not
all of them. I have a feeling that v2.1 will be pretty solid though, I
can certainly attest to the fact that development and bugfixes are an
ongoing process, and there will be continued support for Flash II.

Sure this is necessary? The file routines may already understand such
paths (I don't know, but it's worth looking at).

BTW, I'll post a source I hacked up to actually use a PATH style list.

Just a note to any of you Mega ST owners out there. I tried to install a PC-Ditto II and later an AT-Speed into my Mega 2 ST. Neither worked properly and both crashed very frequently. After much time trying to find out what the problem was (both of the add-ons worked fine on my 1040 ST), I finally heard rumor about some of the Mega ST's having some weak chips. A friend of mine asked about it up on Compuserve, and I finally got the details about the problem. Some of the Mega ST's had weak 74LS373 chips on the motherboard. This was know to cause problems with the ST, such as crashing and bombs, or glitches on the screen. They also could cause trouble when trying to use add-on hardware. If your chips have SGS or SG stamped on them, then they are suspect. I just went down to my local electronics store, spent $1.20 each for two new 74LS373 chips, removed the old chips and installed the new ones (this does involve soldering). My AT-Speed is now up and hapilly running (actually, it is running, and -I- am happy).

I just wanted to spread the word about this problem, as I had never heard about it before. Adios.

Thanks, Steve!

Can anyone tell me how to drop/assert DTR on the extra serial ports
of the TT and the Mega STe?

(I'm trying to add some Fcntl options for modem control to MiNT,
and it would be nice to support *all* of the serial ports).

The moment you use assembler, you give up portability and
compatibility whether it is in-line or separate from the C. Of course
there isn't any _need_ for in-line assembly but I find it convenient
because the argument passing can be left to C. I guess I'll learn to
live without it.

Thanks for the information on Lattice.

Source record: 44488

I had the same problem when reading data I had copied to an atari disk
from the Sun at work. I don't _why_ it happens, but I get around it
by using a program called Cheetah (basically a speedy file copier).
According to the docs, it says it uses its own routines to do disk i/o.
Whatever it doesn, it works and copies files without corrupting them a
bit. Other file copiers may work (??) but I've never tried any others
(maybe some weekend when I get a free second).

The easiest way to build your own Hard Disc, is to use a standard SCSI-Drive
and a SCSI-hostadaptor. There are lots of them on the market (about $100).
Personallly, I`m using an ICD-Adapt., which is very good (and fast !!)

Don`t try to use an (old) ST 512 hard drive. You can`t save money with it !
And it`s too slow !!

Your best bet would be to get a serial EPROM burner. You would probably
have to write a simple BASIC program to send the file to it.

I use the Jounior Prommer from CT magazine in Germany and it seems to
work very well for me. Get a copy of CT magazine and write away for
the kitset (I do not have any left, people borrow them and never return
them to me:( ) so I suggest you ask some of the DE readers for the
address.

Regards and good luck

Roger,

Have you tried STALKER at all. From all reports it seems to do the
job ok. I personally use flash for the remote AS400 and AST links
and find it does ok, it took me a while to redefine the keyboard
but it seems to work ok.

Did you get the VT100 modules from GEnie yet? They work ok with
Flash for me.

There is INDEED a VERY good VT-100/VT-102/"IBM ANSI" emulator out for
the ST. It's called ANSITERM, and it supports 16-color VT-102,
blinking text, etc. If anyone it interested in getting this
shareware program please send a stamped, self-addressed envelope to:

According to my documentation (Latice C 5.5), you can use the special
symbol \@ which generates an unique number for each macro invocation.
Appending this symbol to a label should give you "local labels".

>>to link the foreign code with the present Laser C code. So my question

Laser C doesn't produce DRI format but its own object format (although
their linker CAN link DRI object modules and libraries).

1950. Shared SCSI

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-15 20:54:13 UTC
From: hyc@hanauma.jpl.nasa.gov
Message-ID: <1992May15.205413.22525@elroy.jpl.nasa.gov>
Source record: 44490

Well, it looks like there's no reliable way to get two ST's to talk to each other thru ICD SCSI host adapters. I think I'm gonna wrap a control connection in via MIDI. So, the scheme now:
ST's connected on single SCSI bus, multiple SCSI peripherals online
ST's connected via MIDI
Probably treat the MIDI as a token ring; the node with the token gets to use the SCSI bus. For write operations, a control message listing the device and block numbers written needs to be broadcast to other nodes, so they can invalidate their caching of any affected blocks.

Since it doesn't seem like I can rely on host-to-host SCSI communication, a SCSI disk file can also be used as a shared memory buffer; send and receive control messages again going thru MIDI. With a SCSI RAMdisk, or just a disk with a decent sized on-board cache, the performance should be pretty slick.

Comments or suggestions?

I have a question about HD here and hope if someone can tell me:

I hook up my hard disk which has been working fine in an
AT desktop case to a new tower case.
And what I did was overturn the disk because I place
it upside down last time. Now, when it is properly
sitted (the circuit board is below), the HD is totally junked
reported by CleanUP ST. I thought I might had hit the
drive when I moved around but the when I flip it back
(the circuit board is above), every work fine again.
Why does this happen?
...Thanks

> does not put a parent basepage adress into your basepage).

This is almost true. MiNT certainly does put a parent basepage address into
the basepage. However, the step "use it to locate the parent's saved stack
pointer" is problematic, because MiNT doesn't save registers in the basepage
(and TOS never documented where in the basepage they were saved)!

There's a kludge in MiNT 0.94 to let Sozobon programs work, but this is still
a "dirty" trick and it definitely *will* break in a number of circumstances:

(1) Since Atari never documented the "registers" part of the basepage, they're
free to change it in future versions of TOS.
(2) The child typically doesn't own the memory attached to the parent, so
if any sort of memory protection is enabled the child will get a bus
error; this could happen in future versions of MiNT and/or TOS.
(3) If the parent is swapped out to disk (i.e. if swapping is ever
implemented) then obviously the child will be unable to read its
parent's memory!

So, I strongly recommend that people fix all of their programs to make sure
that they don't try to use this (illegal, undocumented, guaranteed to break)
hack.

Why bother with the MIDI link. Have ST1 write commands and block numbers
to a predefined sector on a disk, which ST2 can then read.

1956. Reading tar:red disks?

Newsgroup: comp.sys.atari.st.tech

Source record: 44399

I tarred gcc files to disks (with ISC Unix) and now I noticed that
I can not read them with my Atari. I have two different tar-programs
but neither can read "raw" disk. All programs I found tried to find
normal directory structure from the disk, but the disks I made
with

```
tar cvfk /dev/dsk/f1q9dt 720 *
```

command have no directory, they are tape images.

So is there a solution?

Please don't forget that newer Ataris (MSTE/TT) have more than one
serial port - and BIOS channel 1 (AUX) doesn't always point to the
"ST compatible" port ("MODEM 1").
Using the new XBIOS function Bconmap (or using Atari's MODEM.CPX),
you can point the AUX channel to any of the serial ports.

Before touching the DTR line, better check if channel one has been
redirected using the Bconmap function:

/* Note:
* Serial ports are (currently) numbered 6 through 9, with
* "6" designating the "normal" (ST commpatible) serial port.
* Using the Bconmap function, one can redirect the AUX channel (1)
* to any of these ports.
* Iorec() and Rsconf() are redirected, too.

```
*
* Bconmap returns the previously selected channel.
* Bconmap(-1) leaves the selected channel unchanged.
* Bconmap(-2) is outside the scope of this article. ;-)
* Bconmap(0) should be used to check if the Bconmap function is
* present at all (it may be part of TOS _or_ may be part of an
* driver for some serial expansion card!)
* If the result is nonzero, Bconmap is not implemented.
*/

#define Bconmap(d) xbios(44,d) /* Note: the result is a LONG! */

int BIOS_AUX_is_redirect(void)
{
if ( Bconmap(0)!=0L )
return 0 ; /* not redirected */
return Bconmap(-1) != 6L ;
}
```

They're mixed up -- the STE has two, 8 bit DMA sound channels.

> Printing chars out doesn't seem to be a problem at all, just
> reading them!

The GEMDOS calls work, but you may be looking for the wrong kind of
information from them.

On U.S. domestic machines, the keyboard is not set up to produce
codes outside the ASCII character set, which runs from 0 through 127.
Keyboards for machines sold in Europe have different layouts that can
produce accented characters, etc., with a single keystroke. With TOS
2 and 3, you can generate out-of-range keystrokes by using the alt
key and the numeric keypad. (There are alternate keyboard drivers
that can change these behaviors.)

Try this program:

```
#include <osbind.h>
#include <stdio.h>
main()
{
unsigned long l;
l = Cnecin();
printf("%08.8lx = %c\n", l, (int) (l & 0xFFL));
}
```

Note that the GEMDOS calls return LONG (32-bit) values, not 16- or
8-bit codes. The format is like this:

```
Bits Meaning
---- -------
0-7 ASCII character code, if there is one
8-15 All 0
16-23 Unique keyscan code (0 if the console is redirected)
```

One set of documentation that I have claims that the following values
are encoded in the upper word:

24 State of right shift key
25 State of left shift key
26 State of control key
27 State of alt key
28 State of caps lock key
29 State of clr/home key (or right mouse button)
30 State of insert key (or left mouse button)
31 Reserved

However, experimentation shows this not to be the case. You can get these values by using the Kbshift(-1) function, which returns the values of those keys encoded in bits 0-7 instead of 24-30.

The unique keyscan code that is assigned to each key on the console makes it possible to differentiate among similar keys -- say, for instance, the 7 on the typewriter keypad and the 7 on the numeric keypad. It also makes it possible to differentiate among the keys that do not correspond to ASCII codes, such as the function keys, arrow keys, etc. For example, function key 1 is 0x003b0000, since there is no ASCII code for a function key.

If you hold down the alt key and press an alphanumeric key, the keyboard generates the correct keyscan code, but the ASCII portion of the key value is 00. Using this information, you should be able to write a keyboard input routine that converts alt-e to an e with an accent acute, or alt-E to an e with an accent grave, if you so desire.

Because 32-bit values are not easy to handle with a C compiler whose ints are 16 bits, the dLibs getch/getche functions return an int that is constructed by shifting the keyscan code into bits 8-15. The resulting int is easy to process in a switch-case construct. See the dLibs documentation and source code for details.

Incidentally, if you're writing a GEM application, don't use stdio or GEMDOS or BIOS to read the console. Use the event manager, which returns keystrokes in a 16-bit format similar to that used by the dLibs getch function. The evnt_multi call and the much easier-to-use GEMFAST evnx_multi call can be used to make the state of the alt/shift/etc. keys available.

1962. Mint - first time of use

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-17 21:42:54 UTC
From: geoffc@zebedee.UUCP
Message-ID: <8635562@zebedee.UUCP>
Source record: 44293

Well I've just got mint 0.94 from atari.archive and here are some first impressions from setting up and using it - I tried to use mint 0.91 once before but I only had 1Mb - with 4Mb its much better !

I successfully setup mint to auto start under neodesk 3 - since some people have been having troubles doing this, here is exactly what I did :

copy neoload.prg into c:auto
copy mint.prg into c:auto
re-order c:auto so that mint.prg is the last thing, after startgem.prg
copy mint.cnf to c: - I did'nt put any program to be auto run by mint at the end (ie: INIT entry) so that gem is started by mint
copy bgacc.acc to c:
edit startgem.inf to autorun neodesk.exe instead of neoload.prg

and this works fine for me.

Now onto the problems ...

Mint seems to work well some of the time and crash quite a lot the rest of the time - it may be that I need to identify what programs it does, and doesnt like to run. Text output seems to be slower than under TOS - noticeably so, even with the fasttext device installed.

I like bgacc quite a lot and I've been using it with mintshel.prg quite a bit; there seems to be a problem with it not closing windows properly so I've run out of windows before (I can't track this down properly though). I have found one definite repeatable problem though:

open mintshel.prg
ls x: - works OK
^d to close mintshel
open mintshel.prg again
ls x: - this time, gives a segmentation error & crashes with 3 bombs.

Every time I get a mint crash I loose the mouse - anyway of turning it back on (neodesk/mint control key set ?)

Finally, is there anyway to preset the font size (eg: to 8x8) in bgacc without having to do shift-select and choose the font size each time I reboot ?

Otherwise, it looks good and I think I'm going to have great fun using it !

The 74LS types can cause trouble regardless of manufacturer. It sometimes helps
to replace them by 74HCT types. You should replace both 74LS373 *and* both
74LS245 (which are positioned in one block together on the PCB).

[... stuff deleted ...]

I too have found this somewhat annoying thing about the MiNT man pages. I
having dug into this problem, but judging from the loads of error-messages the
problem could be that the formatting commands is written as `.Sh' rather than
`.SH' causing confusion in my man-formatter (nroff by Bill Rosenkrantz).

There is several simple fixes such as changing the docs, but I would like to
know whether this is a bug in the formatting of the docs, or it should be
considered a feature that my man-formatter just doesn't recognizes?

If the last is the case, I'll flame the author of the formatter (or not really
flame, since it's a nice piece of work).

Hi People,

I received on Saturday a set of TOS 1.4 ROMs. Unfortunately, no instructions.
The chips were labelled L0, L1, L2, H0, H1, H2. This is what the originals
looked like on my REV.B board:

```
|
| C026160-001
| RP23256 0150
| 6A4 A9
|
| C026244-001
| RP23256 0156
| 6C2 A6
|
| U4 C026145-001
| RP23256 0157
| 6C2 A6
|
| C026163-001
| RP23256 0153
| 6A3 A9
|
| C025246-001
| RP23256 0158
| 6C2 A7
|
| U7 C026247-001
| RP23256 0159
| 6C2 A6
|_______________________________________
```

Anyone know how my new chips match up with this layout? Many thanks in advance
for any help.

Cheers,

1966. UNKNOWN C CALLS

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-18 08:40:37 UTC
From: mark.thomas@rose.com
Message-ID: <1992May18.074039.18973@rose.com>
Source record: 44408

Date Entered: 05-18-92 03:32

I am trying to convert a program for the ST from an unknown C version to Laser C. There are two calls that I m having difficulty with decoding. The first is
setvbuf(stdin, ibuf, _IOFBF, sizeof(ibuf));

This call has 4 paramenter. The closest call in Laser C only has 3 paramenters. I tried:

setbuf(stdin, ibuf, sizeof(ibuf);

However, this call results in an warning that sizeof is being promoted to a long. The documentation says the parameter is an int. What is wrong?
The other call that I have problems with is:

p = strrchr(s,"\\"); where s is a string

Could it be the this function returns a value based on wheter or not a specific string is found?

Any suggestions welcome!

> Could it be the this function returns a value based on wheter or not a
>specific string is found?

The call should be:

p = strrchr(s,'\\'); // so single instead of double quotes

and it returns in p a pointer to the last occurence of \ in s.
And if \ is not in s p will be NULL.

Yes, use MiNT v0.9x with my floppy driver recently posted to c.b.a.st and
tar will then be able to access floppies directly with /dev/fd????? depending
on how many sectors,tracks,sides etc the disk has.

Install the driver and then tar xvf /dev/fd??????.... etc...

1969. Bourne shell for MiNT (new version)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-18 11:30:51 UTC
From: neuhaus@vier.informatik.uni-kl.de
Message-ID: <neuhaus.706188651@vier>
Source record: 44436

Hi.

I have recently posted a message saying that I had ported the bourne shell compatibe shell, written by Kenneth Almquist, from the 4.4BSD to MiNT. I had asked for feedback, so that I could determine whether supporting that thing for more than my private amusement was worthwhile.

Boy did I receive mail!

I have received roughly 30 to 50 mails within one week. Luckily, I had asked for a uniform Subject: line. Anyway, I have removed the backquote substitution bug and corrected the test(1) which comes with the distribution.

I have sent the sources and binaries to comp.sources.atari.st and comp.binaries.atari.st, so they should appear there RSN. For people who can't wait, ftp to ftp.uni-kl.de, and get sh-bin.zoo or sh-src.zoo from pub/atari/mint.

The port is stable on my system. But then, I have 4MB main memory, 520MB disk space, TOS 1.4, MiNT 0.93 ((1L<<10) thanks, Eric!), gcc 1.4, and a level 0 backup.

So you can stop saying "get /bin/sh" to your Subject: line. Thanks for the feedback, though. Some people have pointed me to interesting problem areas in sh.

If you reply, please send mail to neuhaus@informatik.uni-kl.de, not neuhaus@vier.informatik.uni-kl.de. This is a bug in our news software, and I'm not sure when we'll get it fixed. Thank you.

>The moment you use assembler, you give up portability and
>compatibility whether it is in-line or separate from the C. Of course

I think the point he was making was that its better to have your assembly
stuff in a file of its own, and access it via the linker. Its certainly easier
to keep track of what you need to recode this way. The only disadvantage is
that you add the overhead of a function call when you access it. Easily avoided
by moving any loop code to within the assembly code as well.

> Has anyone SUCCESSFULLY created a desk accessory with GCC 2.1 ?

creating desk accessories with 2.1 is no different from any
other version of gcc. you need to follow the conventions, and give it
some heap+stack space in your BSS section. the convention is
documented at the top of crt0.c, in the docs somewhere and in the
sample ACC suuplied in gemlib/test.

cheers,

Manpager works on preprocessed man pages, unlike a lot of Unix versions that run directly on the nroff source code (which is what is in the files you can't process). You'll need to get hold of a copy of nroff and process such files with it first. For example, if I had a man page called dummy.3, I'd do the following to install it:

```
nroff -man -Tan dummy.3 >f:\man\man3\dummy.3
compress f:\man\man3\dummy.3
```

The first line produces a file manpager can display in the correct directory (for me). The second line compresses (archives) the manual page so that it takes up less space (manpager being able to decompress such files on the fly)

SORRY! I've tried that method!!!!! just telling it to set or reset the
bits doesn't work unless you tell it it can have write access to the port.
but once you do that, on and off gibit cause the drive lights to flicker,
the printer strobe to be asserted, and other irritating things like that.
Perhapse I was doing something wrong, but for the first time in over a year,
I have a routine that hangs up properly. See my assembly/C hybrid listing.

Some of you seem to be discussing multiple computers using the same
SCSI drives. I may be getting a second ST soon, and I was wondering if
I could make them work with the same ICD host adapter with the same drives.
Is there any easy way do do this?

>Good idea -- but, if aux has been redirected, how do you control
>DTR? (I have neither docs nor a TT on which to experiment.)

Sorry, I don't know that - this information _could_ be in the "Atari
Profibuch", but I couldn't find it. :-(
Even if I did: Atari didn't guarantee that the additional ports will
remain compatible in future machines (Falcon...)

For the time being, I'd suggest to simply leave DTR alone if AUX has
been redirected.

Eric Smith recently wrote something about adding some Fcntl calls to
MinT (and, hopefully MTOS) that allow hardware-independent control of
the serial ports...

>Also, can you explain the use of Bconmap(-2)?

Okay, here it is:

Bconmap(-2) returns a pointer to a BCONMAP structure:

typedef struct {
MAPTAB *maptab ;
WORD maptabsize ;
} BCONMAP ;

<maptab> points to an array of <maptabsize> MAPTAB structures:

typedef {
WORD (*Bconstat)() ; /* function pointers */
```

```
LONG (*Bconin)() ;
LONG (*Bcostat)() ;
void (*Bconout)() ; /* (I'm not sure this is really a void fn */
ULONG (*Rsconf)() ;
IOREC *iorec ;
} MAPTAB ;
```

This is certainly useful for those wishing to add serial ports: there is now a legal and standardized way to add device drivers to the system.

But I'm not quite sure if Bconmap(-2) is useful for _application programs_ since it involves accessing "kernel memory": possibly not a good idea under MTOS on a TT (but I could be wrong).

On the other hand, the only other way I know to determine the number of serial ports available involves trying to change the Bconmap setting and then checking if the change took place - not a good idea in a multitasking system either.

I do hope very much that MTOS/MinT will provide some solutions to these litte problems...

Is <ibuf> is larger than 32767 bytes?
Possibly sizeof(type) returns a _long_ value if <type> is larger than
that, and a _short_ value otherwise.

1982. How can I revive a color 1040ST bought in early 1987

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-18 21:50:58 UTC
From: mm@didsgn.uucp
Message-ID: <1992May18.215058.4958@didsgn.uucp>
Source record: 44425
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I apologize if this question has already been answered 1000 times but I am
was not familiar with this newsgroup before...

Here is the deal:

I have an almost never used color ATARI 1040st wich was bought in early 1987.
It has 1Mb of memory, color screen and 3 1/2 floppy.
Everything works but the floppy which chokes from time to time while booting.

2 questions:

1) Where can I get the floppy drive check/repaired/replaced ?

2) What must I do/buy to upgrade this machine to a 1992 level and
really do something with it ? (ROMs ? more mem ? add a hard drive ?)

Thanks for everything

>to a predefined sector on a disk, which ST2 can then read.

Mainly because the ST SCSI host adapters I've seen so far have no provision
for bus-arbitration when there are multiple masters. If two STs try to use
the SCSI bus at the same time, things generally lock up on both systems.

Last time I asked ICD about this, they said they had no plans to ever support
bus arbitration, so ... you need an alternate path for control information.

1985. ? printer redirector

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-19 01:47:18 UTC
From: robin@sherwood.Aus.Sun.COM
Message-ID: <1992May19.014718.21779@Aus.Sun.COM>
Source record: 44422

I have an application that prints directly to printer ports.

What I would like to do is "print to a file".

Does anybody have any software that can be run as a resident program that will intercept the printer ports and save the result to a file ?

Can it be done on Atari's ?

P.S.

I have a 1040ST with 3.5" floppy.

TIA,
Robin.

^^^
>`.SH' causing confusion in my man-formatter (nroff by Bill Rosenkrantz).

u might want to check $TMACDIR\tmac.an (or whatever u call it) in nroff.
i might have included a .Sh macro that i used to use (now never). either
comment it out (.\" is a comment at beginning of line) or make a macro
like this:

```
.de Sh
.SH $1 $2 $3 $4 $5 $6 $7 $8 $9
..
```

this will then invoke .SH in place of .Sh. the other thing is to ask eric
what he believes .Sh should do. this is not a "normal" unix -man macro.
i have never seen a manpage with .Sh before (on at least half dozen unices).

the other thing is to put the above macro in a file (say $TMACDIR\tmac.mnt)
and do:

```
nroff -man $TMACDIR\tmac.mnt file...
```

[note: TMACDIR is an environment variable read by nroff for the location
of the macros. at least i think i called it TMACDIR. heck i only wrote the
sucker...]

>If the last is the case, I'll flame the author of the formatter (or not really
>flame, since it's a nice piece of work).

no, don't flame me. i get yelled at enuf :-)

Huh? I just did
fgrep ".Sh" \mint\doc\man*
and found no such commands. Doing
nroff -man fcntl.nr
produces the desired results, with no error messages. (I used fcntl.nr
as an example because it's the longest, most complicated man page, but
others work fine too).

Are you using the manual pages from the MiNT 0.94 distribution? Earlier
ones may have been buggy, I don't know. If so, are you remembering the
-man switch, and are you sure that the TMACDIR environment variable
is correctly set?

I'm using Bill Rosenkrantz's nroff, too, so that shouldn't be the problem
(although I did build it myself, with gcc and mntlib; perhaps a compiler
or library bug is affecting the binary you're using).

>>>>> On 13 May 92 16:21:01 GMT, healy@cod.NOSC.MIL (Mike Healy) said:

Mike> Your floppy might be out of alignment. I know mine is (again)
Mike> so I can no longer read and write ST disks to the SUN. If some
Mike> of the files can be read and then others are corrupt, that
Mike> might be your problem.

Don't go blaming your ST drive that quickly. I've had such problems
in the past. Some files would read correctly on the ST, others would
be corrupted according to our favorite archiver program. When I would
remove a file then the disk space would not all be recovered. In
other words *a real mess!*

Mike> What are you using to read/write the disks on the SUN? Mtools?

I used to use Sun's own `dosmount' but no more (see above problem!).
Switching to Mtools solved the problem! In addition, there is a
version of Mtools which accepts 10-sector/track disks. These, of
course, cannot be formatted on the Sun.

Cheers,

Pure Software, Munich, FRG, has an 68040 capable macro assembler.
Think it's a nice tool.

Distributor is
Application Systems Heidelberg
POB 10 26 46
D-6900 Heidelberg 1, FRG

Sorry, think I'm posting only companies addrs today...

I would keep the monitor and trade-in your 1040ST for 1040STe with 4MB and TOS2.06 installed - a few of the US mail order companies are taking trade-ins.

At least, you can get a replacement drive for US$90 + the old drive from TOAD computers and the TEC card for approx. US$130.

The new version of ANSITERM is out.
Features include:
16 color text
blinking text
full featured auto-dialer
file transfers using XYZ 2.01
pull-down menus

If anyone is interested in getting this shareware program, please send
a stamped, self-addressed envelope, with 50 cents (U.S.) for the disk to:

Timothy Miller
7519 Winging Way Drive
Tampa, FL 33615-1519
U.S.A.

Don't forget the 50 cents for the disk... even if it has to be the
equivalent in a foreign currency.

Well for one thing we don't have the key board to do VT220 emulation, the only
way to do it with Uniterm is to program the Funtion keys, but I also found that
Uniterm does not draw the boxes like Flash does, what gives..

Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Arriving soon at atari.archive.umich.edu:

Patchlevel 20 of the MiNT libraries. This version will support gcc 2.1,
and incorporates Scott Bigham's patches for Sozobon 1.33i (thanks,
Scott!). There are also miscellaneous bug fixes, including some
very important fixes to osbind.h. (see my next message if you want
details).

2000. SERIOUS bug in gcc and MiNT libraries

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-19 18:53:54 UTC
From: 7103_2622@uwovax.uwo.ca
Message-ID: <1992May19.145354.1364@uwovax.uwo.ca>
Source record: 44439
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

There is a horrible bug in the header file osbind.h for both
the MiNT library (patchlevel <= 19) and the gcc library
(patchlevel <= 80). The binding for Bconmap is incorrect. The
Xbios function number for Bconmap should be 0x2c, *not* 0x2b.
0x2b is the function for DMAwrite!!!!

DO NOT USE THE Bconmap BINDING AS PROVIDED IN osbind.h. DOING
SO COULD CAUSE DAMAGE TO DATA ON YOUR HARD DISK!!!

This bug has been corrected in patchlevel 20 of the MiNT libraries.

STE DMA chip problems...

This problem was only with one type of DMA chip and in machines manufactured in 1990..

PLEASE back up you Hard Drive first, you could end up loosing the lot..

You need to Write to the Hard Disk to find this problem, ie, just changing a file name is one simple way...

Try this many times and after the machine has been on for some 24 hours or more..

One friend found his after 2-3 days..

If you have the faulty chip your Directory will get screwed..

Faulty chip Part No. C025913-38.. (now obsolete)..

Now Replaced with C398739-001A..

One funny thing is that this chip C025913-38 was fitted to the first ST's..

Atari has told me that this is a Free Fix...

I have just fixed a few of the STE's with chips provided free by Atari Ozz, it seems to me that these new chips have better buffering..??

> University Of Essex.	(Shakespeare)
> woocm@essex.ac.uk	Disclaimer: I never wear fluffy pink slippers.

$FFFFFC00 is the address of the IKBD ACIA control register AND status register.
When you write to it you get the control register and when you read from it
you get the status register. Since you can't read the control register
it helps to know that the original contents is $96 (I think).

Similarly $FFFFFC02 is the both the data in register and the data out register
depending on whether you read or write to it.

Its hard to give any further advice since you don't say what you're trying to
do and what is going wrong. Reading the Motorola MC6850 data sheets should
help.

2004. Mint scrolling

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-19 19:54:04 UTC
From: geoffc@zebedee.UUCP
Message-ID: <5825587@zebedee.UUCP>
Source record: 44294

Some comments on the scrolling speed of mint, including some observations and a bug I've found with bgacc.acc.

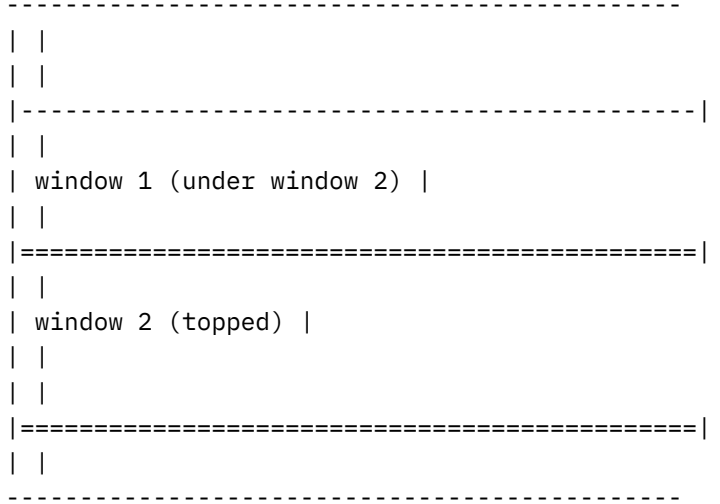
I should add first of all that these comments I'm making about scrolling have been made when I've been running 'rn' from the Mercury UUCP package - it's what I do quite a lot on my ST (and why I wanted Mint so that I could do other things as well).

Scrolling under mgr is *very* slow - you can see each word appear at a time - even if you make the window full width (so that there is no horizontal clipping), it's still slow. Also not all vt52 characters seem to be emulated under bg (eg: inverse text, clear screen).

Scrolling within a window under bgacc is faster - more so if you can use a smaller font so that it doesn't have to do window clipping. All escape chars I was using worked fine.

However, both of these were slower than running rn directly from the desktop (or rather Neodesk) which fills the screen much faster. One time I did try launching mintshel from bgacc and doing 'zoo t mint094b' and then running rn from Neodesk (so that bgacc ran as a background task). The scrolling was then roughly as slow as running rn directly from bgacc, until the zoo completed at which point the scrolling leapt up in speed - this leads me to wonder if some of the slowness of the scrolling is due to bgacc 'time slicing' all the time between tasks ?

Onto the bug I've found, if you have two windows on the screen from bgacc overlapping each other (both full width but only part of the one at the top of the screen visible) then the scrolling in the 'untopped' window doesn't always work right. Setup is:



if you do something that writes output to window 1 quickly (like ls -lR \)
then window 1 will scroll correctly. However, if you do something that
writes output to the window slowly (like rnews or zoo t) then the window
doesn't scroll correctly - what happens is that the line just above window 2
is scrolled up but what would be the next line doesn't appear. The effect
of all this is that one line scrolls up the screen. Topping window 1
results in it working fine.

Sorry I've gone on so long but I'm quite excited about Mint - despite the
problems I've had and the fact that it crashes programs more than my old
TOS 1.0 machine did its a really great product.

Cheers

Geoffrey

I recently read somewhere that atari changed the interpretation of the return value of Sversion(). My documentation says it should be interpreted like

highbyte = $15
lowbyte = $00 --> version 0.21

The article I saw claimed it would now be: version 0.15

Is this correct?

They can't it is in the hardware of the 68K documented by Motorala that
adress 0x4L contains the PC for an external reset and adress 0x0 contains
the initial stackpointer. The chip have to find them somewhere not so.

Even if atari wanted to revector 0x4L they can't unless the use another
type of CPU. (Haven't heard any rumours of any RISC used in ST compatibles
so I guess we can forget about that for the time being :-)

I hope so.

Look at it this way:

Under TOS (Which MiNT is Not), when zoo prints its chit-chat to the screen,
EVERYTHING STOPS until that text is printed - zoo included. Once the text
is output, zoo continues on it's merry way.

This may LOOK fast to you, but it's actually slow. It's like running over
a modem and thinking your programs are running slowly just because there
output is arriving slowly at your end.

(this post makes some assumptions about bgacc that may not be true (re
buffering), but the result is probably certainly worth considering)

net.rule #1
Don't accuse net.gurus for faulty files before triple-checking

As indicated, Eric was correct that the MiNT manpages is correct and indeed they go through nroff without a hitch, which I verified last night by formatting them all.

The problem was a little real though, since it proved that the man page for csh in my version of the tcsh distribution contains mixcased formatting commands. Perhaps someone in charge of that (hint hint Eric) will fix it, even though the One and Only True Editor could easily take care of it, with a simple macro.

With humble apologies for any confusion caused

> This call has 4 paramenter. The closest call in Laser C only has 3
>paramenters. I tried:
>
> setbuf(stdin, ibuf, sizeof(ibuf);

Let me tell you, what my Turbo-C reference manual says about setbuf
and setvbuf:
void setbuf (FILE *fp, *void *buf) ;
int setvbuf (FILE *fp, void *buf, int type, size_t size) ;
setbuf sets the buffer related to FILE fp to buffer buf, rather than
to the automatic allocated buffer. The minimal size of buf is given
through the constant BUFSIZ (in stdio.h). setbuf may only be used on
open Files and before the very first I/O operastion!
If buf is a NULL-pointer, setbuf disables I/O buffering on FILE fp.
setvbuf performs a similar task, with the following additions and
differences:
type specifies the kind of buffering and should be one of the
following constands (defined in stdio.h)
_IOFBF - I/O fully buffered, every read operation on fp tries to read
a complete buffer of size 'size'. While writing only complete buffers
are physically written to the file.

_IOLBF - I/O line bufferd

_IONBF - I/O not buffered

if buf is a NULL pointer, setvbuf tries to allocate a buffer of size
'size' by calling malloc.

> The other call that I have problems with is:
>
> p = strrchr(s,"\\"); where s is a string
>
> Could it be the this function returns a value based on wheter or not a
>specific string is found?

char *strrchr (const char *s, char c) ;
strrchr scans the string s for the first occurance of the char c,

beginning with the last character of s. So strrchr finds the last
occurance of c in s.
strrchr results in a pointer to the position of c in s, or NULL, if
nothing could be found.

2016. NeoDesk / Gemini comparison? and HSC

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-20 12:25:03 UTC
From: tony@microware.co.uk
Message-ID: <957@mwuk.UUCP>
Source record: 44308
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hi,

Can anyone provide a summary of the main differences between NeoDesk 3
and Gemini 1.21?

I have Gemini 1.21, and installed it on my hard disk OK, but with 1 meg
of RAM I don't have enough memory to run Heat'n'Serve C under it, so
currently I still use the standard TOS 1.4 desktop.

I guess I really need to upgrade my ageing STM to 2.5 meg.......

Gemini doesn't seem to be strictly a *replacement* desktop, but a
desktop program which is run or auto-run from the standard desktop.
Therefore both desktops are active and using memory. Is it possible to
set up Gemini so that after VDI and AES are setup, control goes straight
to Gemini *instead* of the standard desktop. This would surely save a
bit of memory. Which way does Neodesk operate in this respect?

Does NeoDesk have a CLI along the lines of Mupfel?

The Gemini docs warn of a problem with Sozobon C to do with a memcpy()
bug. Does this problem affect HSC 1.33i too?

Any other relevant comments gratefully received.

Tony.

Hi there!

I`m desperately in need of hardware information for the Atari
range of computers. Also, I need diagnostic info/software. I have
a very sick machine!
If anyone can help, please e-mail me or send stuff to my home
address. I will gladly refund any postage costs incurred.

Thanks in anticipation.

Artie.

i know its weird but the correct way to write the above is

```
if { -e d:\file } == 1
echo it is there
ef
echo it is not there
endif
```

cheers,

I have used UNITERM, both in VT100 and in VT220 modes while connected
to our VAXes here, running BSD. I don't understand the reluctance of
our NZ friend to use one of the finest terminal emulators going.

Is there anywhere out there where I can get my hands on some atari st hardware and software documentation. I am basically looking for atari specific assembly language trap codes etc. and the addresses of all interfaces, ports, rams, roms, and otherwise on an atari 520 STfm. If there is an ftp site that has some of this info, please point me to it. If there isn't anything lurking around on internet, can someone point towards any good books??

thanks in advance,
andrew

>
> setbuf(stdin, ibuf, sizeof(ibuf);
>
> However, this call results in an warning that sizeof is being promoted
>to a long. The documentation says the parameter is an int. What is
>wrong?

setbuf provides a subset of the functionality of setvbuf. The stream,
buffer pointer and buffer length are the same, the third parameter
to setvbuf is a constant that specifies the buffering mode:

_IOFBF full (block) buffering
_IOLBF line-oriented buffering
_IONBF no buffering (setbuf(stream,NULL) does the same)

sizeof returns size_t, and this is usually an unsigned long. The buffering
routines only accept buffer sizes so that the index can be stored in
an int -> a simple cast to int should be ok.

:
: They can't it is in the hardware of the 68K documented by Motorala that
: adress 0x4L contains the PC for an external reset and adress 0x0 contains
: the initial stackpointer. The chip have to find them somewhere not so.

That's true for the 68000 but not for the following ones (010, 020, ..):
the base address of exception vectors can be changed from 0 at start to
any other location: so it has to be 0x00..004 and 0x00..00 when starting
the processor (for each Hardware Reset) but can be elsewhere while running !

But that's generally true that you can expect to find resvect at 0x00..04 !

2023. Re: NeoDesk / Gemini comparison? and HSC

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-21 07:07:55 UTC
From: monnier@disuns2.epfl.ch
Message-ID: <1992May21.090755@disuns2.epfl.ch>
Source record: 44314

In article <957@mwuk.UUCP>, tony@microware.co.uk (Tony Mountifield) writes:
: Hi,
:
: Can anyone provide a summary of the main differences between NeoDesk 3
: and Gemini 1.21?
:

a few details and some more Dollars (or francs or whateve) (!!)

: I have Gemini 1.21, and installed it on my hard disk OK, but with 1 meg
: of RAM I don't have enough memory to run Heat'n'Serve C under it, so
: currently I still use the standard TOS 1.4 desktop.
:
: I guess I really need to upgrade my ageing STM to 2.5 meg.......
:

If you look carefully in Gemini docs you''l find that you can configure
it (Gemini) to start some or all programs in Overlay: when you launch the application,
Gemini quits (well, not really, it lets a little (<20K)
programm), starts the application and when you quit that app, Gemini automatically restart:
that's quite useful with 1M and a hard disk !
(but with today's mempory prices, that would be even better to get
to 2.5M or even 4M)

: Gemini doesn't seem to be strictly a *replacement* desktop, but a
: desktop program which is run or auto-run from the standard desktop.
: Therefore both desktops are active and using memory. Is it possible to
: set up Gemini so that after VDI and AES are setup, control goes straight
: to Gemini *instead* of the standard desktop. This would surely save a
: bit of memory. Which way does Neodesk operate in this respect?
:

No, you can't start Gemini before the desktop. But there are prgs that
let you autostart Gemini: you won't see the desktop any more. For the memory problem: the
desktop doesn't use so much memory (don't try to compare with Gemini) ! Neodesk starts
"exactly" the same way as Gemini (and has the same Overlay capability) !

: Does NeoDesk have a CLI along the lines of Mupfel?
:

I don't know much about Neodesk !

: The Gemini docs warn of a problem with Sozobon C to do with a memcpy()
: bug. Does this problem affect HSC 1.33i too?
:
: Any other relevant comments gratefully received.
:

Just one regret: Gemini's CLI misses some test and loop constructs !

1. Please fix your mailer. Use <80 columns; I had to manually adjust
your lines.

2. You want to get the Atari ST Profibuch. It's in German, but I know
of a translation in Dutch of one of the older prints (which probably
is of no interest to you since Dutch is even worse than German) som
maybe there's even an English version. One of the authors regularly
pops up in this newsgroup. It's Julian F. Reschke. For more info,
give the net a yell and he might hear you.

3. Well, why haven't you got the book yet? Hurry up!

BTW. It's dead cheap for those 1.5 Kpages!

Could someone please email me (or tell me where to ftp it)
zoo version 2.00 please. I want this specific version because I have
a .zoo file which was created by zoo2.00 and zoo2.1 will not unpack it.
(I had unpacked that file several times with my old version of zoo, which I
recently deleted when I got zoo2.1.)
The .zoo file doesn't seem to be corrupted according to fiz.

I have run into the same problem. I have found that the second FAT is
blank. The first FAT appears to be ok. When I copy the contents of FAT
1 to FAT 2, then I can recover most of the files. This doesn`t make any
sense, since I thought FAT 2 was unused!? The first file written
to the disk is usually corrupted. I have tried formatting on the ST,
Sun, and a pc.

> Your floppy might be out of alignment. I know mine is (again)...

Not likely. My drive is aligned and functions normally with other disks.

> What are you using to read/write the disks on the SUN? Mtools?

Yes.

> Mike Healy
> healy@cod.nosc.mil

On a similar note, I have had zero success running a group of utils from
Atari.archive that supposedly let you convert raw->tar->st and vice-versa.
These little progs bomb when I try to run them. I have TOS 1.4 (1.2?). I
don't remember the name of the stuff or who wrote it except "unixflop"
sticks in my mind.

When I ran into this problem, I assumed it to be caused by running out
of memory -- I only had 2 Meg. Isn't 4 Meg pretty much a requirement
for compiling large programs? I know I can do small programs, but large
ones didn't seem to like GCC.

From: dud@cbnewsf.cb.att.com
Message-ID: <1992May21.174633.25485@cbfsb.cb.att.com>
Source record: 44322

Hi,

I haven't exactly been deluged with offers from people willing to sell their old TOS 1.4 ROM's. I got one comment from somebody who recommended something called a "DUALTOS EPROM set" that enables you to have two versions of TOS ROMs resident simultaneously. I can't imagine why you'd want to do that, I don't even have ONE set of ROMs, and the gentleman doesn't answer email requests about where do I get the bloody object code to put in the EPROMS on this hardware board.

Somebody else recommended Wes Newell's ROM adapter board. I called Wes up, he seems a nice sort, but he doesn't sell ROMs, only the adapter board.

So I'll try another tack.

There has been recent mention of a document in German that describes the internals of the ST. Where can I get a copy? In English, preferably, but if not, I'll ask a German co-worker if she can translate it for me.

In the mean-time, can someone e-mail me the address ranges of the various versions of EPROMS? I understand that early versions (1.4 and earlier) addressed from FC0000 to FFFFFF. Where does 2.x live?

Thanx,
Bill Dudley

Maybe it's just the same problem I had one week ago:

I had misplaced a trailing backslash at the end of the env-var TEMP and
that caused strange error-messages in obviously correct header-files. After
deleting the backslash everything worked fine.

I had a similar problem with gcc 1.40, indecipherable parse errors
in include files, and found that it was my Gulam environment variable
TEMP that it didn't like! The distributed example Gulam scripts give
TEMP with a trailing backslash, like

setenv TEMP g:\

this confuses gcc mightily, try

setenv TEMP g:

2036. Program crashes on quitting.. help!!

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-21 19:23:54 UTC
From: chris@spuddy.uucp
Message-ID: <1992May21.192354.23480@spuddy.uucp>
Source record: 44330

I have written a sizable application using Laser C V2 on the Atari.
The application has a resource file containing a menu bar and some
dialog boxes (made with thhe Laser C RCP).

At present, the progam runs ok and does not crash. HOWEVER, if I modify
the menu bar in the resource file (using Laser RCP), save the
resource file, and recompile the application, it will crash with four
bombs when I quit.

More info:

The crash happens somewhere in the gemdos(4C) call that Laser makes when
the application quits (I have traced this far).

The crash ONLY happens under TOS 1.0 - not TOS 1.2 or above (however, my
application must be able to run under all versions of TOS).

The crash ONLY happens when running in low rez, not in medium or high.

Please can anybody suggest what is going on!!! It is driving me mad!

chris.

Reply to me in this newsgroup, or mail to the above address, or if
you are feeling really friendly, phone me on 0394 410459 and I'll
get you a pint or three :-)

At the request of some German users, this is been changed in STalker
3.02 (available real soon now), i.e., it raises DTR when it starts up.

2038. Copyright/spreading of C'T programs (question for Germans)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-21 19:53:20 UTC
From: jensting@ee.ic.ac.uk
Message-ID: <1992May21.205320.9107@cc.ic.ac.uk>
Source record: 44326

Hi

I have just found the FTP site(s) fpor c't source code (hint, the address is in the back of the magazine, on the pages listing DFU sites..).

Now, do *you* know what the status of source/binaries is? These programs are printed in source code form in a magazine which retains copyright. The readme files at the FTP server say that the source code is only intended for improved understanding of the articles.

I, for one, sure plan to try to compile/assemble some of this stuff. Then, can I give the binaries/source away? Maybe mergin in a *strong* copyright statement asserting c'ts claim to the rights..

If someone could give me a reason to believe that I wouldn't get blacklisted by the German police for it, I'd like to collect all the ST software and send it to terminator.cc.umich.edu (the server I found c't stuff on sure is *slow*)

In other words. some of you Germans who talk to c't people regularly on BIX (or whatever), please check, hmm?

Thanks

Jens

I don't know much about Neodesk, but I use Gemini all the time (I rarely go back to the standard desktop any more).

First, to my knowledge, there is no way to save any memory used by the Atari desktop. The code is in ROM (of course), but I don't think it uses all that much RAM. The only way I know of to prevent the desktop from taking its share of RAM would be to prevent GEM from loading (through an infinite \AUTO program), but this would make Gemini useless since it uses GEM.

You can make Gemini come up automatically at boot time simply by installing it as an automatic application in the "Install Application..." menu item on the Atari Desktop. That's how I do it and it works great.

I also have only 1 MByte of RAM, but have never had a problem with Sozobon C. I would imagine that HSC 1.33 is the same in this respect. Don't forget that Gemini gives you the option of loading programs as overlays (replaces Gemini in memory), or not (resides in any memory Gemini leaves available). I always have to use overlay mode since I only have 1 meg. It takes a little longer to load such programs, but it sure saves a bunch of memory.

Just my $0.02

2041. Problem with ATSpeed C16

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-21 22:19:03 UTC
From: sakari@laureline.cs.hut.fi
Message-ID: <1992May21.221903.26794@nntp.hut.fi>
Source record: 44329

I bought an ATSpeed C16 for my Mega ST about a year ago and have been using it regularly - I'm using it to post this, in fact.

After some months of usage, I started getting unexpected crashes under Windows (protected, a.k.a. standard mode). Also, the keyboard acted rather strangely while in protected mode under DOS. I wrote about this to my German supplier, who said they would have to check the setup at THEIR place. Natural, but just not on for me. Also, at about the same time I gained access to a 386 PC, and that became my Windows machine.

Now I'm starting to get keyboard problems under non-protected-mode DOS, too. Specifically, the Alt/Ctl/Shift status seems sometimes to stick, that is, I type Alt-F and G in succession, and it comes out as Alt-F and Alt-G. I also re-checked Windows; everything works but the mouse - the rodent just stays put at the center of the screen.

Things appear to center on the keyboard and the mouse. I wonder whether anybody else has had the same problems. Several people have recommended changing the 74LS373's on the motherboard to cure unexplained Mega ST problems. However, I have never had any problems with Spectre GCR, and Spectre is reputedly extra sensitive to precisely to those chips.

Thank you in advance,
s.a

2042. Re: RS232ENC.PRG dropping the DTR

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-22 00:29:40 UTC
From: woju@keep.fantasy.sub.org
Message-ID: <H.ERlGcKPIfw6@keep.fantasy.sub.org>
Source record: 44335

In <876ykB5w164w@sys6626.bison.mb.ca>, Trevor Cordes writes:
#When I boot up my TT, the DTR light on my modem lights up. When the
#computer gets to RS232ENC in the auto folder, the modem's DTR light goes
#off. If I go into STalker 3 and order a hang-up (dropping the DTR), the
#DTR light will come back on and work as it should. How come RS232ENC is
#dropping the DTR when it initially boots? My computer's a TT030/4
#w/TOS 3.01. My modem's a ZyXEL U-1496E (14.4kbps). I've also heard of
#someone else having the same problem with RS232ENC, so it's not just my
#modem/computer. Any ideas?

I donnot have the source, but i cloud imagine, that the programm turns the
DTR off while initializing the Traps and IRQ vectors so the outside world
knows DO NOT go and send DATA keep quiet. Soem Modems will ignore this, but
Your Zyxel shouldnt. This is quite a good feature, so in a case the machine
gets reseted by an bombing program, or something else, the modem will hangup.
If You don't need this just use at &d0 so the Modems will ignore the DTR totaly.
(This works with a DISCOVERY 2400 C, and conforms with HAyes as far as I know)

#
#I work with a NeXTStation and for this machine I have a Syqest HD.
#
#I want to connect sometimes the Syquest to my TT (via SCSI) but the
#Syquest-Cable I got is a SCSI-2-Cable, so my question is, if there
#is a commercial adaptor to connect SCSI-2 with SCSI-1 and where can I
#get it?
#
#Is it possible to connect two computers to one HD?

YES !
But both SCSI Adaptors (not the cable, the SCSI-buscontroler!) should be
able to work with multiinitiator, which just tells that each ID can start
a transfer (This is normal SCSI but is not always implemented,
due to the degration to an Harddisk Interface :-((( )
The next is able to do this (The internal Adaptor is ID 7, which is often used
for the Adaptor itself). But I don not know if the SCSI Adaptor in the TT
is able to handle this . is it a Sysquest 555 (this HD is used for the ST/TT too)
It shouldn't make any Problems.

Something that isn't in the picfmts guide (and probably shouldn't be), is exactly how to DISPLAY one of these images. Other than using the spectrum slideshow program. Something like a C call would be ideal. Then we could generalise it to use TTLow on a TT or CPU munching hblanks on an ST[e].

In <7939@uqcspe.cs.uq.oz.au>, Warwick Allison writes:

#>Does anybody have a subroutine that converts the value returned by a
#>call to "getenv ("PATH")" to a path that looks "Atari-ish"?? The
#>string I get back looks like:
#
#> /dev/c//\bin:/dev/d//\dtp\wp
#
#>I would like it to look like:
#
#> c:\bin,d:\dtp\wp
#
#
#Sure this is necessary? The file routines may already understand such
#paths (I don't know, but it's worth looking at).

Actually this is done on purpose (I think it is POSIX which requires it)
with the MINT lib this will cause no Problem. Just call execvp and Your
Programm gets found, if it is along the Pathes on the PATH variable
prior starting a Program the Environment gets converted again, and insde
crtinit.o it gets into POSIX. This will do no Problem with the LIB, because
there are PATH converters (unx2dos & dos2unx) which will be called by the
Library if needed. With MINT and your (root) drive U:
there are actually /dev/a/ and such stuff :-)

So please let it as IS.

But my question still is Why is errno not set on EOF (with ttys) by the
fillbuf routine at MintLib Pl 19 (I haven't looked at PL 20)

What about running that C as an overlay programm? This would cause Gemini
to exit while you're running C and re-loading Gemini afterwards.

>I guess I really need to upgrade my ageing STM to 2.5 meg.......
Do yourself a favour: Get 4MB ;-)

This is not possible (at least for Gemini)...

>Any other relevant comments gratefully received.
I *personally* think Gemini is a lot better than Neodesk. Gemini offers
a lot of features I've never seen in Neodesk (for example the XAcc and
AV/VA-protocols, not to mention ARGV-Support etc. pp). Furthermore,
Gemini is cheaper than Neodesk ;-)

I'm getting more "disk may be damaged" messages of late, and one disk drive (of 3) couldn't format a disk without giving this message (the other drive formatted without talking back).

Is there some sort of standard alignment disk that I can use to evaluate my drives? I assume a head stepper motor sometimes marches to some other tune and that's the reason I'm having trouble, but I'd like to know which one to shoot. The drives are the internal guys in 1040STs and one SF314 w/Epson mechanism.

Thanks for any information....

Yes. Consider that:

TOS GEMDOS
0x0305 (3.05)? 0x1900 (0.19)
0x0306 (3.06) 0x2000 (0.20)

The last GEMDOS revision only contains very minor changes. Why should they
have incremented the version number from 0.25 to 0.32??

BTW: it's also documented in the TT TOS Release Notes.

For the menu bar TOS 1.0 keep a background buffer of a third of the
screen buffer (~ 10k) to backup the image of the screen portion.
In med & hi rez the menu bars are tiny but in lo rez they are bigger in
mem amount.
It's possible that form_alert can also use this buffer!!
At this moment I don't now how to increase the amount (maybe alt buffer).
But i could try to look at my old documents for more information.

Harry

P.S.: don't worry about my english. I'll learn it sometime else.

I don't think any c't people are on BIX. At least, I've never seen the term "c't" before, and I moderate the atari.st conference on BIX. If you know the names of anyone, I can find them if they are there, and will be happy to rely messages.

>details).

The Heat-n-Serve/Sozobon version is also at atari.archive, under the name
mnthlb20.zoo in either atari/mint or atari/new, depending on how soon you
look for it. You may have seen an announcement for version 19a; ignore it.
I released it about two days before Eric released version 20. If you actually
got the 19a release, replace it with this one.

Notable with version 20 is that the printf/scanf routines in libm1.a have
been merged into libm.a, so that you can once again include the floating
point library with just the `-f' flag.

Well done for describing the problem in such detail. As you probably know,
when a menu is drawn the screen memory underneath it is saved in a static
buffer. In TOS V1.00 this buffer is rather small and it is quite easy to
have a menu which is too big for the buffer which then overflows corrupting
god-knows-what. The problem is usually occurs in low resolution because
the same screen area takes more memory to save because of all the colours.
I think I read somewhere that the problems start when a menu is bigger than a
quarter of a low resolution screen. Incidently the same buffer is used for
form_alert()s so be careful with those as well.
There may be a patch available to increase the size of this buffer, but
failing that either
a) State in the documentation that the program doesn't work in low
resolution with TOS V1.0 - If it is a serious application then few people will
be using it with this setup anyway.
b) Split the menu bar up into more headings each with less entries
(Although it may then be too wide for low resolution anyway)

c) Abbreviate some menu entries in the biggest menu (Or have a special resource file with abbreviations which is only used with TOS 1.00 in low resolution).

>was then roughly as slow as running rn directly from bgacc, until the zoo
>completed at which point the scrolling leapt up in speed - this leads me to
>wonder if some of the slowness of the scrolling is due to bgacc 'time slicing'
>all the time between tasks ?

(btw i haven't tried mgr yet, only bgacc and mw2.)

if you run `top' in a window you can see that GEM (ie bgacc or mw2
in top's listing) is eating huge amounts of CPU time even when the
computer is otherwise completely idle. so i think the reason is not so
much the taskswitching itself but more that GEM and MiNT don't know each
other yet, ie GEM still `thinks' its alone and happily wastes cycles
busy-waiting for events from the user... :-(

so... if atari is doing their homework this should be fixed with
`multitos'. (at least i do hope so!!) until then you can a) either
simply stay away from GEM and use /dev/fasttext + a shell that knows
about job control (or better, has anyone thought about virtual consoles
or maybe `screen' for MiNT?), or b) try to improve things a little by
playing with bgacc/mw2's priority -- although screen updates will of
course be more `jerky' the lower you make it. (i ususally `renice -10'
it after opening all my windows, but the exact value surely depends on
your setup and taste.)

Source record: 44259

In <957@mwuk.UUCP>, Tony Mountifield writes:
>Hi,
>
>Can anyone provide a summary of the main differences between NeoDesk 3
>and Gemini 1.21?
>
The really great thing of gemini is the console window with mupfel in it.
Neodesk has lots of neat features like desktop notes and displaying volume
labels (or their own format labels) in the window. Splitting the window in too
and builtin icon manager. If you are used to them you have a hard time to
work without them.

Unfortunately Neodesk is not so stable they use some pretty dirty tricks and
on some accounts are very inefficient. The protocol they developed for
communications with accessoires is not very usefull and not widely accepted
(can't say anything more
about it because of the non-disclosure acrement I signed). The gemini protocol
is PD and more robust (it works well in the acc's I've seen) and widely accepted.

>I have Gemini 1.21, and installed it on my hard disk OK, but with 1 meg
>of RAM I don't have enough memory to run Heat'n'Serve C under it, so
>currently I still use the standard TOS 1.4 desktop.

doesn't gemini have an option to unload itself when a program is started?
I think it is called 'overlay'.

>Gemini doesn't seem to be strictly a *replacement* desktop, but a
>desktop program which is run or auto-run from the standard desktop.
>Therefore both desktops are active and using memory. Is it possible to
>set up Gemini so that after VDI and AES are setup, control goes straight
>to Gemini *instead* of the standard desktop. This would surely save a
>bit of memory. Which way does Neodesk operate in this respect?
>
Exactly the same way because there is not other way. The TOS desktop program
is located in ROM the RAM that is taken by the system is for AES and is only
for screen buffers and some internal variables. Don't forget that the desktop
is just another program the runs under AES and is completely located in ROM.

TOS 1.4 lets you autostart a program so you can make it look like you have
a different desktop coming up automaticly.

>Does NeoDesk have a CLI along the lines of Mupfel?

Yes but it is a seperat product (not that expensive) it works but Mupfel
is much much more powerfull

>Any other relevant comments gratefully received.
>

My opinion of Neodesk is based on long practical experience on a 1040 STf with TOS 1.0. Currently I no longer use Neodesk because of the bugs I encountered and I now have TOS 2.06 in my Mega STE. Gemini I tried on several ST computers but never for long periods I now only use mupfel as a CLI for my UUCP software.

Just to point out where I stand.

Well, if the cases have the second acsi port on the ICD host adapter
exposed, it should be easy. You have to take one drive apart and change the
ID number. I know the Syquest, so I'll describe hor to do it with it.
At the rear of the Syquest is a block with shorting resistors. Consult
your Syquest manual, and repin it to scsi id 1. When you're hooking the
dives up, put the Syquest first, and remove the terminating resistor pack.
(Actually, I'm not 100% sure this is necessary with the acsi connections,
but I think it is. It definately is for scsi.
Your ICD software will recognise both drives, and you're off and running.
If you want to seperate them again, you really only need to hook up the
terminating resistors, as ICD software will boot from a scsi id other than
0, unlike atari's.

Two options:

1) use two computers connected over midi/rs232 with mx2net/anet installed
(note that anet is slow and unreliable , don't know about mx2net)
Software is available at atari.archive.
Maxspeed midi: 38K bps rs232: 19k bps

2) set unit number of 1 drive to 0 and the other to 1 and daisy chain then
over the DMA/ACSI port. (Assuming you have a ST lying around)
Use desktop to copy, speed about 600 Kbyte - 1,5 Mbyte per second

Hi,

I am trying to write a program that logs phonenumbers I dial trough
my modem and the connecttime for these calls. I think that should
be possible by installing my own routine in the MFP carrier detect
interrupt. (that is for the connecttime logging, catching the phonenumber
is another easy to solve problem I think)

QUESTIONS:

- How should I program a routine for the MFP interrupts should I return
with rts or rte.

- How can I check the status of the Carrier?

- Is the interrupt given on carrier detect raise/lower or both?

- Did anybode wrote such a program already? (No need to invent the wheel twice)

Please reply by email, I will post a summary later.

Thanks in advance for any help.

The posted question asks if we're going to do an SST for the Mega STE. (There are two radically different flavors of STE!)

While we've found a way, it's up to us to determine if we will sell enough to be worth the VERY expensive R&D. Remember, if we funnel money into this project, there are others that won't get done.

No decision "for sure" yet on Mega STE. Regular STE we have the board layout for done.

Can anybody here help with this question, please?

==========
atari.st/main #5877, from erethakbe, 317 chars, Sun May 24 23:38:57 1992
There is/are comment(s) on this message.

TITLE: BASH
I recently downloaded BASH in my attempts to find a CLI I liked.
However, it wants files to be named .bash_login, which would be a
piece of cake on UNIX, but my ST truncates to .BAS. Has anybody
had any success setting this up on the ST? I'm probably overlooking
something obvious, but I can't find it.

The BASH referred to is from a file called TOSBASH.ZOO. Supposedly, it
is GNU's BASH shell, ported to run under the TOS filesystem. But, if it's
looking for names like that listed above, it isn't TOS-ish. Can anybody
offer suggestions or workarounds? Thanks.

Didier,

You have to tell us which TeX version you use. If it's CS-TeX, just be sure
to have tex.poo in the same directory where the formats are/will be.

I suspect it isn't since you mentioned setenv.prg.

Hello.

At last, I have managed to aquire MiNT 0.94, and now that I have it running, I have two questions. One relates to programming, which is why this message also appears in comp.sys.atari.st.tech, and the other relates to how BGACC works.

1. I have a terminal program that I have just about finished the second version of, but after installing MiNT I've noticed that the terminal mode is MUCH slower than before. I currently use Crawio() to put text on the screen and Bconin() to get text data from the modem. Does the ST have a faster output routine than Crawio()? If I would like to continue using my own program, I'd better make it faster. Up until now, it has handles V.42bis compression with an actual connection rate of 2400 baud.

2. Is there a way to prevent programs that BGACC.ACC starts from taking up all the memory the system has left? Also, is there a way to pass a command line to programs started in the same manner? I've noticed that BGACC.ACC doesn't wait for command lines at all. I like the windowing that it does, though.

I should mention that I uncommented the line "HARDSCROLL=25" in the MINT.CNF file so that hardware scrolling would be active. The desktop I am using is Gemini 1.21 for the moment, and my system has two megabytes of RAM. After everything is up and running I have 940K free. BIOS buffering is also set to ON.

I hope someone can help me out with either of these questions.

Fwrite() is enormously faster than Crawio, at least under MiNT (probably not under TOS; and TOS also doesn't provide any way to make Fwrite do raw output :-( ). The reason is simple -- you can transfer a whole lot more bytes per system call, and system calls are expensive.

> 2. Is there a way to prevent programs that BGACC.ACC starts from taking

The answer to both questions is the same: run a CLI in BGACC windows. Then you can launch programs with the "limit" command (see the MiNT utility package) and/or use whatever builtin features the CLI has to limit program sizes.

This would be fine, except for one point of confusion on my part. Serial data (on output) must be one character at a time in most cases. For regular terminal mode, where the user types as I am typing now, each character is sent to the modem as it is typed, since the program would not be behaving correctly if it waited for an end of line. On serial data input, the problem is a little different. A routine could be used to do the following:

/* This is just a explanation, rather than a code fragment. */

Check to see if the serial port is waiting to give data to the computer.
If it is, add the data to the string about to be sent.
If it is backspace or delete, adjust the string accordingly.
If it is a CR/LF, send the string using Fwrite().

Check to see if the modem has more data to give to the computer.
If so, go back to the first (indented) step.
If not, send the string and start all over.

/* End of possibly incorrect explanation. */

The only real problem is determing what the end of the string is, since prompts from BBS systems and line number in their editors are not followed a a CR/LF. So, I guess a string could either be considered terminated when there is a break in the data from the serial port or a

CR/LF is received.

Does this seem right to anyone except me? :) Output while typing would still be one character at a time, but things like ASCII uploads and sending function key macros or the date or the time would be faster than it is now, I think.

If I have made some horrible, evil, insidious mistake in my reasoning, don't hesitate to tell me...:)

2079. Color Monitor Problem

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-26 04:38:12 UTC
From: steveg@cseic.saic.com
Message-ID: <6677824@MVB.SAIC.COM>
Source record: 44273

I've got a circa 1986 Atari SC1224 color monitor that's beginning to have problems and was wondering if someone can help. I turned it on the other day and noticed the sides of the image were being 'pinched' inwards:

```
---
) (
---
```

I tried tweaking all of the pots inside that I could find to no avail. (Using a plastic tweak tool and staying far away from all nasty high voltage in there). Any suggestions? BTW, the picture tube says "Hitachi" if this makes a difference.

>want to do that, I don't even have ONE set of ROMs, and the gentleman
>doesn't answer email requests about where do I get the bloody object
>code to put in the EPROMS on this hardware board.

Some older programs don't work with tos version 1.2 and higher, so it's
quite good to be able to switch back to tos 1.0.
The problem with the code itself is the fact that the tos is under copyright
of Atari. It is illegal to copy any tos-version and burn it into eproms !!
So contact your local Atari dealer, he can sell you ready-for-use roms

>In the mean-time, can someone e-mail me the address ranges of the various
>versions of EPROMS? I understand that early versions (1.4 and earlier)
>addressed from FC0000 to FFFFFF. Where does 2.x live?
Not quite correct. The versions 1.4 and older are located from
$fc0000-$fefff (192 KB)
Tos 2.xx is from $e00000-$e3ffff (256 KB)
So if you have a 'normal' 520/1040 ST or Mega ST you'll need a special board
to install tos 2.06 in your computer. (In germany these boards are sold for
about $100, including the roms. But it won't help you, because it's the german
version of the tos)
The older tos versions are sold as
a) 6 roms with 256 kbit
b) 2 roms with 1 Mbit
You can put the 6 roms in every ST, but the 2 1Mbit roms only in newer STs.
(Or you have a bit of work to do, soldering a 74LS11 (or 12 ??) and some
wires.....)

2081. C'T program source code. Answer(s) from c't editor(s)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-26 13:32:16 UTC
From: jensting@ee.ic.ac.uk
Message-ID: <1992May26.143216.5625@cc.ic.ac.uk>
Source record: 44275

OK, Damen und Herren (girls and boys)

The answer from the c't editor(s) is that while the stuff is available for anon FTP, c't still has copyright and insists that the stuff on the FTP servers is only made available as a service to readers of c't. (Non-readers will have a hard time figuring out how to use the source code, anyway..)

My conclusion is that if the maintainers of the terminator.cc.umich.edu archive were to write to c't (address at end of reply 2), they should be able to get a mirror directory up and running with the official blessing of c't . Of course, no-one said that using the programs is going to be easy, *and* any posting by us c't readers of extracts from the c't articles would be very clear-cut violations of the copyright on the magazine.

When you do dive into it, note that the comments are often in German, with very strange schemes for storing non-american chars. This will probably screw up compilers/assemblers (it even screwed up the printer program on our SUN4 for an Atari ST assembler program!).

I haven't looked much into the code available yet, but the f-line emulator in ct9004 clearly stands out as a nice program to have, I'll get a co-processor and report back in, say, two months ;-)

Lea: "I love you!" Han Solo : "I know." 'The empire strikes back'

Here is my original letter to c't, and the responses

========== letter ==========

Hello

(excuse me for mailing in english, but my german only stretches to reading)

What is the excact status of program sourcecode from c't, with respect to copying of source and binaries? I know that material printed in the magazine is copyright c't, but what restrictions are c't putting on copying of electronic copies of listings from disks or FTP-servers ?

The reason I'm asking is that some of the Atari ST programs deserve a wider audience, e.g. the extremely active groups in the USENET

community. Virtually no american enthusiasts have the required knowledge of German, so c't remains practically unheard of.

While there is a case for preventing commercial expolitation of the programs, non-commercial use would seem fairly harmless.

Jens

---------- reply 1 ----------

>What is the excact status of program sourcecode from c't, with respect >to copying of source and binaries? I know that material printed in the >magazine is copyright c't, but what restrictions are c't putting on >copying of electronic copies of listings from disks or FTP-servers ?

All material from c't and also the listings are strictly copyright by our publishing house Verlag Heinz Heise.

>While there is a case for preventing commercial expolitation of the >programs, non-commercial use would seem fairly harmless.

Right! But we do not want to work for anyone else but for our readers. Many of the programs cannot be used properly without the knowledge of the c't arcticle they are based upon. We would have to expect an overflow of our telephone hotline if we gave the listings into public domain.

So, any form of broadcasting the listings is prohibited with the exception of the sources authorized by c't. We do not mind if listings are passed to single other persons in the private environment. But we expect those person to read the respective c't article.

Readers may of course use algorithms and library functions as part of their own applications even if they are commercial.

Best regards
Christian Persson

---------- reply 2 ----------

>*Are* the sources on the FTP server authorised for broadcasting ?? Not >being a lawyer I don't know, but what prevents a person from the USA >from setting up a mirror image of the ct directory from one of the FTP >sites?

There is always a difference between what's legal and what's possible.

The respective FTP Servers are authorized. To apply for authorization just send a message to Michael Wilde (mw@ix.de). It is not a problem - only a little formal act to make clear who is the owner of the copyright.

>Do you mind if I send this letter to the USENET group >comp.sys.atari.st.tech ? I'd also post the result of `archie ct` which >gives a rather solid hint as to where the stuff *is* available.

I don't.

>PS With the USENET community there isn't too much risk of them getting
>on your telephone hot-line, most of the people are in the USA anyway..

We know that. But Email questions would be just as bad. we are 22
editors and each of us is already spending at least 1 hour per day
in the average with technical support of readers and non-readers!

Best regards
Christian Persson

HANDY HINT #1 for all experimenters with different software
packages. Get a copy of Sysmon, with English docs, and learn how
to use it. It can be set to watch fsfirst, fopen and setpath, and
you can figure where and what files a program is actually looking
for.
For debugging your own programs, it looks also very handy, though
I haven't used it for that yet. All in all, an invaluable addition to
the hacker's toolbox.

The checks in the mail Karsten, I promise. (Sysmon is shareware,
and written by Karsten Isakovik(sp?). It is very professional, reliable,
an supports all system calls up to the TT. Hopefully, a multitos version
will come out, but maybe there are bettter ways to do it under a multi-
tasking environment. Eric's debugging code does a similar function.

True!, Perfectly true! - No more to be said
but

[ Added Note: Many early programs written before TOS 1.4 came out
would do a warm start simply by

Supexec(0xfc0000);

where 0xfc0000 is the RESET subroutine address. When later TOSes came out
this address changed to something like 0xe00000 (I am here quoting from
memory) so the early programs then failed to work (they would "bomb out").
The "sure way(?)" to effect a warm reset on 68000 machines is to "look-up"
(in Supervisor mode) the reset subroutine pointer (long) at memory address
0x4L and then to Supexec() it. Here is some suitable C-code that will do
either a cold (or warm) reset - depending on your keyboard response to a
prompt. Compile with Mark Williams C with

cc -Nrcrtsg.o -VSMALL -o reset.tos reset.c

for a really tiny reset utility. Actually you can get it off atari-archive
where it is named RESET. W. Alan B. Evans
[ wabe@ukc.ac.uk ]
]

#include <osbind.h>
main()
{ register long ssp; char c;
Cconws("\r\n COLD-RESET:x QUIT:q WARM-RESET:[default] ? ");
if ((c=Cconin()) == 'q' || c == 'Q') Pterm0();
/* We must be in Supervisor Mode to look up priviledged locations */
ssp= Super(0L);
```

```
if (c == 'x' || c == 'X') *((int *)0x420) = 0;
if ( *((long *)0x426) == 0x31415926L)
/* Now do the reset */
Supexec(*((long *)0x4));
/* If all works we'll never get to here - but if we do it is wise
to cancel Supervisor mode */
Super(ssp);
}
```

> regular terminal mode, where the user types as I am typing now, each
> character is sent to the modem as it is typed, since the program would
> not be behaving correctly if it waited for an end of line.

Yes, that's true. But in fact, the simplest way to think of the problem is as follows:
if (the user typed anything) {
read(everything s/he typed)
write(it to the modem)
}
if (the modem has data waiting) {
read(a whole bunch of characters, preferably all that are there)
write(what we just read to the screen)
}

Under MiNT, there are a variety of options for doing these things. A simple option is the Finstat() system call, which tells you whether there are bytes waiting to be read. If so, you would use an Fread system call to attempt to read a whole bunch of bytes (say, 32K). Fread will return the actual number of bytes read.

Some important points:
(1) I suggested the use of Fread (the GEMDOS system call) rather than fread (the C stdio library function); the latter does some extra buffering that will probably only get in your way.
(2) The modem file must be set to RAW mode before making any Fread system calls; this is done with the Fcntl system call.
(3) Your program must be a "MiNT domain" program. This just tells MiNT that it's OK to do the right thing with Freads from terminal devices, so that it doesn't try to do the compatible (and brain damaged) things that TOS does. You can do this in one of two ways:
(a) use the MiNT library; it's done automatically for you
(b) use the Pdomain() system call: put
Pdomain(1)
somewhere before any Freads.

If you really want to get fancy, you could use Fselect or the O_NDELAY option to Fcntl in order to eliminate unnecessary Finstat() calls, but

in practice I don't think this would be necessary even at 9600 baud.

From: rdf@pinet.aip.org
Message-ID: <1992May26.202420.5442@pinet.aip.org>
Source record: 44281

I am trying to write a program that will use a tablet through the RS232 port. I have figured out how to read the tablet and convert the info to x,y and a button press. Can someone point me to either an example source file or some documentation on how to feed this information to the mouse pointer so that writing on the tablet will act as if the mouse was moved?

In addition what is the best way to make this a tsr or da so that it always traps the data from the RS232. I realize that I can't use the serial port for a modem when this is installed, but the port is physically in use anyway so I don't think this will be a drawback. I assume that something like a mouse accelerator would be a good model. Thanks...

2088. PC-DITTO.....?

Source record: 44283

A problem for the hardware people:

I just upgraded my ST from 2 to 4Mb using 4 chips of the 1M*4bit kind. The problem is that the upper 2Mb only work correctly if the display memory is not located in that area. If the display is located there, the screen shows a lot of blinking garbage. Everything seems to work fine if the display is in the lower 2Mb.

Has anyone else made a memory expansion using 4Mbit chips?

I sure would like this to work. My ST would then have 64 chips for 2Mb and another 4 for the other 2Mb :-) BTW: It used to be a 1040STf.

Bart Schuller.

This is a classic TV fault - don't touch ANY pots inside as it will add
to your repair bill to have to reset them to where they should be.

Any competent TV technician should be able to fix it, although they may
be a little reticent if they can't get a service manual.

BTW : The fault is called 'pincushioning' and it's usually caused by
component failure. Why pincushioning? Take a look at the shape of an
overstuffed pincushion sometime! :-}

>would a programmer hardwire a call to another shell in there?

One can use _shell_p to install a shell's command routine; that way, you can give system() calls by writing to _shell_p. If you want a listing, you perform system("ls"), if you want to have fun (well, not really) you issue system("\rm -fr /").

However, if you want to enter an interactive shell which system() call do you make? Correct, you start a shell... Mind you, programs should of course call for the thing written in the environment variable SHELL, not bluntly "sh.ttp".

Hope this helps, J.

> other yet, ie GEM still `thinks' its alone and happily wastes cycles
> busy-waiting for events from the user... :-(

At least with MW (don't know about BGACC), this is the result of MW's polling strategy. Basically, MW runs in a tight loop doing evnt_multi() calls, waiting for GEM and timer (!) events. If a GEM event arrives, MW processes it (doing nothing else). If a timer event occurs, MW does an Fselect() to see if any of its children has pending output, and then reads from their pseudoterminals.

It should be immediately obvious where all these cycles are going ...

Apparently, with the current MiNT-unaware GEM, there's no better way to do things like this.

> so... if atari is doing their homework this should be fixed with
> `multitos'. (at least i do hope so!!) until then you can a) either

I hope so too ... but I'm not so sure that I will get MultiTOS, since the next computer I'll by probably won't have an Atari label on it. (To keep off the flamers: I have owned my ST since 1985, and I intend to keep it until I can get a decent UN*X workstation for the same price I paid for the ST).

My father has been using Atari 8-bit computers for years. He uses
LJK Letter Perfect for word processing. Recently he bought a 486
with Word Perfect on it. He has a ton of documents remaining in
the Letter Perfect format that he would like to convert to Word
Perfect format. We are pretty sure that we can get the files onto an
ibm computer. However, we don't know how to convert the files. Is
there a utility somewhere in some archive that can help us out?
We don't even have to go directly to Word Perfect. It would be nice
to convert them just to straight text. Please send answers to the
E-mail address below. Thanks for your help.

I've had similar symptoms when I upgraded my Atari 520STfm from
0.5 to 1 MB. When the video area was in the newly added RAM, it
showed a lot of flickering pixels. Further testing showed that it
was not the video that didn't work, but the memory contents were
changing, i.e. I really saw my bits flickering on the screen.
The solution was to shorten the 0V cable and to add a second 0V
cable. After I did that according to the recommendations I got
from the company that produced the memory expansion, it worked
flawlessly.

Oops, sorry. You're right, Fselect isn't yet reliable on the rs232 port, unless you put a timeout on it (an Fselect on one of the modems, with no time out, will hang forever if no data is available :-( ).

Another way to do the read without taking up much CPU time would be to use two separate processes, one which reads from the keyboard and one which reads from the rs232. But I'm not sure it's really worth going to that much trouble. A loop with an Fselect and a 20 millisecond time out won't eat up very much CPU time.

In MWC and Sozobon/HSC it's just 'global'. When using GemFast (under Sozobon/HSC), each of the fields in the global[] array are also aliased to gl_whatever names, such as gl_apid, gl_apversion, etc. Here's a little piece of code I use to be compatible with Turbo, MWC, HSC, etc....

```
/*------------------------------------------------------------------------
* Link rshdr and rs_trindex into the AES global array.
*------------------------------------------------------------------------*
{
#ifdef __TURBOC__
extern GEMPARBLK _GemParBlk;
register long *plwrk = (long *)(&_GemParBlk.global[5]);
#else
extern int global[];
register long *plwrk = (long *)(&global[5]);
#endif
*plwrk++ = (long)(&rs_trindex[0]); /* -> gl_apptree */
*plwrk = (long)phdr; /* -> gl_aprsrvd */
}
```

[I posted a message about a program that crashed when quitting if
a menu was too big].

Many thanks to Leo Hendry and the many people who mailed me about this.
It does appear that the ST was crashing due to the GEM screen buffer
not being big enough. I have trimmed my menus and the problem has gone
away.

I am amazed that a bug such as this could slip though into the
production operating system of the ST!

Source record: 44102
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have a 80MB SCSI hard drive w/ICD Host adaptor. I ran CleanUp ST on my D partition and it showed that some of my files had bad characters. The files were located only in 2 subdirectories of the root and the characters in the files were changed from upper case to lower case (eg. CC.TTP -> cC.tTP) while some files were named: llllllll.lll. Plus, some of the directory data within the 2 subdirectories of the root was corrupted. Has anybody ever came across this problem and knows what causes it. I'd like to avoid this situation again.

I eventually just killed the 2 directories, copied the other directories to another partition and zeroed the D partition; then I put the other directories back (the 2 bad ones I can recover from floppy).

Other pertinent info: TOS 1.2; Running NeoDesk 3.02.

The only thing different from my normal usage is that I recently tried out the XCONTROL.ACC for awhile (any connection??).

Any help is appreciated,

I am interested in the Pure C compiler, formerly Turbo C. Fans of Pure C
are invited to email me their opinions regarding the following:

1. Is it fast?
2. How fast?
3. What is your impression of the debugger?
4. Can you set breakpoints with the mouse?
5. Will all features work on a 2.5 MB system?
6. There is no question 6.
7. Can you build the MiNT libs with it?
8. Can you use your own editor in the IDE?
9. Can you use GNU make in the IDE?
10. If not, how good are the editor and make facilities?
11. Can you launch the compiler from a CLI, or does it have to
be run from the desktop?

Thanks for any and all responses.

From: "Gerry O'Rourke"
Message-ID: <1992May28.150140.20700@nt.com>
Source record: 44116

I have a problem with my Atari 1040FM + Hard Disk that someone may have encountered before. The disk is a RHODIME RT300T, connected to a Supra adapter. I am using Version 3.11 of the driver software.

The disk is partitioned into two 16 Meg & one 10 Meg sections. Things were fine until partition C: began to fill up. I noticed that files I had copied onto C: last month were missing when I looked a few days ago.

I had previously used Reorg to compact & reorganise the partition. This gave me no problems until there was about 7-8 Megs on the C: partition, when Reorg freaked out & thrashed the FAT. I re-formatted the disk & copied the files back. Now I find that utilities I used last month are gone.

GET INFO reports that there is 8.13 Meg used, with 2.9 Meg free. I used DLII to check the partition & it reported that the directories were bad. It also found 1552 lost or crosslinked clusters. It looks like the files are/were there, but the directory entries were wiped over by new files. When I tried to recover (using DLII), the prog reported that there was not enough entry space?.

Is there a known bug with the Supra software that causes this problem?
I have tried to get newer versions of the Supra utilities, but Supra are really hard to contact, & I can't find them on any sites.

I am using TOS 1.2, are there known bugs which can cause this ?

Please post all replies here, as I don't have an E-mail address (yet).

Regards

Gerry O'Rourke

> the printer strobe to be asserted, and other irritating things like that.
> Perhapse I was doing something wrong, but for the first time in over a year,
> I have a routine that hangs up properly. See my assembly/C hybrid listing.

The code I posted came from a program that has been running for several
years, and is identical to the code that I included in my Atari Explorer
series on serial port programming. If it were broken, surely I would have
heard before now.

My suspicion is that either you didn't call Ongibit/Offgibit with the same
arguments I did, or your copy of Laser C has a bad entry in its osbind.h
file. (Bugs in Laser C are not unheard-of.) If you were making the drive
lights flicker, you definitely were tampering with something other than
bit 4. Are you sure you were using Ongibit/Offgibit and not Giaccess?

The whole point of the Ongibit/Offgibit calls is that you don't have to
worry about details of getting read/write access to the port registers. No
assembly language is required.

Ongibit readers the contents of register A, ORs it with the value you
supply, and writes the result back to port A. Offgibit reads the value,
ANDs it with the mask you supply, and writes the result back to port A.

To drop the DTR signal and hang up the modem, Offgibit(0xEF) reads the
value of the register, ANDs it with 0xEF, and writes back a value that is
identical to the original except that bit 4 (DTR) is turned off.

Ongibit(0x10) reads the value, ORs it with 0x10, and writes back a value
that is identical except that DTR bit 4 is turned on.

To be fair to Atari, this bug was fixed a long, long time ago; TOS 1.0
is ancient history. I know, people hate to pay money to upgrade; but
my TOS 1.4 upgrade was the second best investment I ever made in my ST
(the first best being expanding to 4 megabytes) and I would *strongly*
encourage everyone who still has TOS 1.0 to upgrade to a newer version.
TOS 1.2 isn't quite so buggy, but upgrading to 1.4 or 2.X will still
bring a very noticeable speed benefit to hard disk users.

2112. SCSI problem

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-28 18:38:59 UTC
From: anhalt@curtiss.seas.ucla.edu
Message-ID: <7248@lee.SEAS.UCLA.EDU>
Source record: 44114

Hi there, I just bought a 200MB Maxtor LXT200S SCSI hard disk and I have not been able to get it to work on my atari 520ST. I have tried two different SCSI adapters (supra and the one inside the Atari megafile 44 removeable). Atari's formatting software gives me fatal errors and will not let me select the drive to format it, supra's software returns "SCSI error", and ICD's tells me dma time out. I know the drive works (I was able to get it working on my friend's amiga, with his supra adapter, worked great), I know the adapters I have work, and I know the cables works, so why doesn't IT work? Please send email if you have any ideas about why this is and how to fix it.

Thanks,

James Edward Anhalt, III

2114. Tandberg TDC 3360 tape drive

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-28 19:32:32 UTC
From: geoffc@zebedee.UUCP
Message-ID: <6318414@zebedee.UUCP>
Source record: 44138

I've got the possible opportunity to buy a tape drive but before I do
so I'd like to work out if I can interface it to my ST and use either tapebios
or mt_bin recently posted to do streamer backups of my ST.

The device in question is an ICL S1 streamer tape unit, a modular set of
parts for a DRS300 minicomputer (there are separate boxes for processor,
power supply, hard disk, etc).

On the rear of the box is a connector marked 'SCSI' which certainly looks
like a standard SCSI connector. Also on the rear is a power supply socket
for daisy chaining all the power together (from the K3 power supply unit).
On the front is a set of DIP switches which (I think) are for changing the
SCSI address.

Inside the box is a fan, a fairly large circuit board (not proprietry - it's
(c) ICL) and a Tandberg TDC 3360 streamer tape. Unplugging the streamer
tape inside reveals that it has a standard hard-disk type power connector
and a 17x2 IDC cable socket - it's this cable socket that confuses me !

I figured I could just remove all the innards to just plug the streamer tape
mechanism straight into my hard disk drive. The hard disk setup I have is:

```
---------------------- -------------------------
| ICD DMA->SCSI board |-----SCSI--------------| NEC 114Mb SCSI h/d id 0 |
---------------------- | -------------------------
|
-------------------------- --------------------
| ICD SCSI->RLL board id 1 |---| 30Mb RLL h/d LUN 0 |
-------------------------- --------------------
```

The ICD board is connected to the RLL drive with 2 IDC cables (one data,
one control - I think) and the cable that went into the streamer tape is
the same size as the wider of the cables that goes into the RLL drive.
However, on the RLL board the only spare socket is the smaller size (so I guess
I would have to daisy chain the wider cable if I had another RLL drive).

Any ideas as to what I've found and whether I could wire it up ????

AdvThanks,

Geoffrey

For one thing don't use the Long drive cable that ICD push, use a 18" one,
also get one of the newer DMA chips, Part No. C398739-001A, I don't trust the
older DMA chips Part No. C025913-38 , these are the ones that cause all the
problems with the STE...

Also turn off write caching, I also get the same problems, but these are just
my suggestions to fix the problem, you could also try a different booter,
ala Atari HDX5 or Supra, I do have some doubts about the ICD one, even though
its the best there is....

The DMA chip would be about $15us....

2120. SOZOBON QUERY

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-28 23:35:40 UTC
From: Rick Applegate <rapple@cix.compulink.co.uk>
Message-ID: <1992May28.233540.18717@demon.co.uk>
Source record: 44120

A question or two on Sozobon -

Background:
I have Ian L's Heat & Serve version. I downloaded for a cheap way to learn C. The docs on the compiler are OK, but there are quite a few gaps that my experience cannot fill.

While extending a program one day that was running happily I obtained the error message Stack Overflow. Didn't seem unlikely, I had a lot of open files and was going down about 4/5 levels of subroutine with large variables. (Now that may not be good style, but I am learning. However, no matter what the style the compiler should serve, not dictate.) No problem I thought, I'll increase the stack size. Errr. how?? Maybe I'm being unobservant but I couldn't find any way of doing this in the docs.

In the process of trying to overcome this I found a newer version of the compiler on the atari archive at umich.edu. I downloaded this in the hope that either the docs would be better or that the compiler would deal with the code in a better fashion. Well, docs were no better so I just tried to install the compiler over the top of the existing setup. That didn't work either. Make didn't seem to drive it correctly at all. So... is there an easy way to install version 2 of the compiler over the heat & serve version? Is there a newer version of the heat & serve? Incidentally Ian if you read this I thought it a VERY good install process, better than a lot of commercial installs I've come across. Well worth the effort.

Thanks in advance for any help

Rick Applegate.

>emulator in ct9004 clearly stands out as a nice program to have, I'll
>get a co-processor and report back in, say, two months ;-)

That I can help you with, having a coprocessor for a month now. The story so far: At first I was a kind of shocked by the little gain of speed: last term's project about finite elements (mainly multiplications and additions) sped up to 50%. This was done using the normal Pure C library which in case of the presence of a 68881 uses it instead of having the calculations performed by the 68000. Obviously that means a permanent loading/unloading of FP0 (and FP1) from/to memory, so the FPU is used very unefficiently. Next I discovered that by switching on the 68881 option I could convince the compiler to produce lovely code which uses all the FPU registers and generates nice line F calls. Not knowing about c't 4/90 I started to write my own line f emulator, but didn't finish it because of lack of knowledge about the 68020/68881 protocol. When I read your message I immediately downloaded the mentioned file and tried to get it running. (I did even find the appropriate magazine in the heap.) Unfortunately the code dealing with FMOVEM commands is buggy, I had to fix quite a bit and there is still a good chance that not everything is allright. Anyway, it worked fine in the end, but it is definitely slower than the standard Pure C library. I have to admit that my own emulator is a bit quicker (and longer) than the one from the magazine but you can still see that the standard library beats it.
Here's a table of benchmarks for the afore mentioned program (or do you spell it "programme"?):

without cache	with cache
68000 used by library	3'17''	2'11''
FPU used by library	1'33''	0'58''
line F & emulator	2'17''	1'20''

The CPU's & FPU's clock is always 16MHz (I'm using the speeder HBS 240).

cu Martin

PS: I can't post the emulator, otherwise the gateway people get angry.

Just a bit of a disagreement here. I've been using the ICD cable
for over 4 years without a problem. Also, have used the write caching
for almost a year. No problems there unless you forget how it works and
turn off/reboot, before the write is finished.

> Is there an easy way to install Sozobon v2.x over the HSC version?

There's no easy way to install Sozobon (the real one, from the Sozo crew), that's why HSC was born in the first place. My make will run their compiler, but it probably won't work well the other way around. Other than make, there isn't any interchangability between their programs and mine. (Oh, AR is interchangable too). Thanks for the compliment on the install program, btw. It's the only part of HSC that I can truly take credit for.

> setting the stacksize

It should be documented in DLIBS.DOC (it certainly is in the upcomming v1.40 HSC release, but I think it was there already). Basically, you just define a variable in one of your source code modules. For example:

```
long _STKSIZE = 10240L; // set stack to 10k
```

If you're used to msdos or other compilers, this is counter-intuitive, as stack size setting is typically a linker option.

Speaking of that, I've been thinking of MAKING it a linker option in future releases. On thing this would buy would be the elimination of APSTART.O and MINSTART.O, because if I had the linker involved in setting the stack size, I could do it in such a way that the stack could be dynamically resized at startup time, even in a DA. But, a lot of existing code that uses the _STKSIZE method would stop working. Thoughts?

> stack overflow

In current versions, you'll get a spurious stack overflow error if you call GEMDOS, BIOS, or XBIOS functions while in supervisor mode. That'll be fixed in the upcoming release.

(Er, that is, you *can* get spurious stack overflows when in super mode; it doesn't always happen.)

Message-ID: <1992May29.081722.10@bra.isnet.inmos.co.uk>
Source record: 44049

I'm having problems using a TEAC 3.5" external drive on my Mega ST2, and I was wondering if anybody out there can help.

Most of the time the drive works fine, but now and then it shows the current disk/folder as having no contents. This happens on disks formatted on this drive and on disks formatted on my internal Cumana drive.

I get this problem both when using a fileselector from within an application, and from the desktop. Pressing ESCAPE from the desktop sometimes fixes things, but sometimes doesnt.

For the record I'm using TOS 1.2 with Neodesk 3.?.

Any ideas?

Thanks

>1. Is it fast?
>2. How fast?

Yes, it is blazingly fast - and it uses file caching to minimize (slow) I/O.
Benchmarking it is a waste of time: a source of 10.000 lines compiles in 20-30
seconds tops.

>3. What is your impression of the debugger?

It's not as cool as Think C's debugger for the Mac, but apart from that it's
the most useful debugger I've ever seen.

>4. Can you set breakpoints with the mouse?

Of course you can.

>5. Will all features work on a 2.5 MB system?

All features will work on a 1 MB system.

>7. Can you build the MiNT libs with it?

Dunno, but guesso.

>8. Can you use your own editor in the IDE?
>9. Can you use GNU make in the IDE?

There are two versions of all the stuff, a commandline as well as an
integreated version.

>10. If not, how good are the editor and make facilities?

The 'make' (called project) is not as powerful as normal make; the editor is
ok, and the environment has online help for Pure C, C, ANSI libs, TOS/AES/VDI
libs, and a nifty thing called 'project help': if you've compiled your file
once you can press HELP while on a user-defined function and the editor will go
to the definition of that function, etc. etc.

>11. Can you launch the compiler from a CLI, or does it have to
> be run from the desktop?

You can run it from anything.

>
>Ongibit(0x10) reads the value, ORs it with 0x10, and writes back a value
>that is identical except that DTR bit 4 is turned on.
A big problem with On/Off-gibit is that the original documentation in
the developers' kit was wrong, and every set of docs I have seen slavishly
repeats this wrong documentation. It says something like Ongibit(n) "where n
is the bit you want to set", and identical wording for Offgibit(). What Steve
has written above is correct; I worked it out myself by reading the ROM
listing after a terminal programme I was working on would crash whenever I
tried to do it a la documentation.

>>>>> Regarding Hard Disk Problems; Gerry O'Rourke adds:

Gerry> When I tried to recover (using DLII), the prog reported that
Gerry> there was not enough entry space?.

It seems that DLII does not appreciate weird directory entries, and
then gives the above answer (repeated quite often, actually). That is
why I wrote my own disk traversal routine. What I found out?
Parition C:'s root directory has one cluster beyond the normal end of
my files with junk on it! Virtually no one sees it, eg. gulam or
desktop, but DLII balks and my program works.

2130. Gemini 1.21 problem with HSC

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-29 13:57:45 UTC
From: tony@microware.co.uk
Message-ID: <964@mwuk.UUCP>
Source record: 44134

Hi,

I have a problem trying to use the Heat'n'Serve C in conjunction with Gemini 1.21 in 1Mbyte of RAM.

Because of the limited RAM, I need to specify that MAKE.TTP should be run in overlay mode. However, by doing that, MAKE does not inherit any of my environment variables.

Just to be doubly sure, I have defined the env vars I need both in ROOT.ENV, for use by GEMENV, and also in MUPFEL.MUP. Mupfel confirms that I do indeed have the required values, and if I call MAKE without using overlay mode, it inherits them successfully. However, I then have insufficient RAM for the C compiler. :-(

It appears that RUNNER.APP is the culprit - either it is not receiving environment vars from Gemini, or is not passing them on. Or perhaps, even worse, Gemini does not pass them out to RUNNER.APP.

The Gemini manual does say that environment variable are lost when using overlay mode. I can understand that temporary env vars will not be preserved, since Gemini starts up from scratch after the overlay program finished, but I do need the overlay program to inherit them.

Does anyone have a solution to this problem (apart from more RAM! :-), such as a modified RUNNER.APP ?

Juergen, you can get TOS Release Notes (and about anything else from the ST or TT Developers package) directly from Atari. You no longer have to be a registered developer to get most of the stuff. In the US, contact Gail Bacani at Atari Developer Support at (408) 745-2022. Mail address is 1196 Borregas Avenue, Sunnyvale, CA 94089.

>can't read German?

Only if you can read english :-) (The program menus are in english,
but the online help text is in german).
As I've said before on the net, don't let the german language deter you.
For most german texts an english equivalent can be found (for example,
for the ANSI C libraries there are obvious english replacements).
For the remainder some guessing and perhaps a dictionary will suffice.

I am no wizzard in german, but it has never been an obstacle in using
the program.

2136. ST boot sector missing

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-30 01:09:46 UTC
From: JoelES@cup.portal.com
Message-ID: <59797@cup.portal.com>
Source record: 44135

Help!!! Lost communication with Megafile 30 hard drive with Mega 2 computer. A read-only sector editor shows the boot sector (sector 0) to be all 00's. All files and directories appear intact, but the drive icon never appears, and the Atari Hard Disk utilities V 5 reports device 0 as "identification unavailable." Maybe a virus cleaned out the boot sector. Anyway, lots of critical files are inaccessible. Yes, I admit it! I failed to back them up!!! If anyone knows what needs to be in the boot sector of a Mega 30, and has any idea where I can get a sector editor that will let me rewrite the boot sector, I will be in your debt. PS: it seems the computer cannot recognize the drive, since another utility reports cylinders to be zero, sectors per track to be zero, etc. The drive is otherwise OK, and I can read any of its sectors with utilities I have. I just can't access it from the desktop, and it will not boot from the hard drive anymore. Again, thanks to any Atari tech expert out there who knows the intimate details of their disk format!

2137. GCC 2.1 - Can't compile desk accessories???

Newsgroup: comp.sys.atari.st.tech

This should "work" as a desk accessory (but freeze the machine):

```
main()
{
while (1);
}
```

Correct?

When I compile this with GCC 2.1, it bombs (2 bombs) at boot (ie. run) time.

Has anyone SUCCESSFULLY created a desk accessory with GCC 2.1 ?

> Gemini's RUNNER.APP doesn't pass env vars to MAKER

I've never used Gemini, so I can't supply a direct solution. A workaround might be to use MAKE's $(SETENV) command in the .INICMDS: section of the MAKE.INI file. The delivered MAKE.INI has some commented-out $(SETENV) commands to use as an example, have a look. This won't allow you to set env vars differently for each run (like setting CFLAGS= in the env and accessing it from within makefiles), but it will let you set the PATH, INCLUDE, and LIB vars so that the compiler will run from MAKE. (The .INICMDS and $(SETENV) combo is a holdover from the days before I had written GEMENV to handle things.)

Nope, that should do just what it did, lock up the machine. For accessories to multitask with the rest of the system, you have to have AES calls, since the AES is the dispatcher for multitasking. The minimum DA would look like:

```
main()
{
int msgbuf[8];
appl_init();
while (1) {
evnt_mesag(msgbuf);
}
}
```

```

The following is what I pulled out the last time this thread came up.
This is pretty long, and some of the information is repeated, but some
isn't, so look through it carefully.

From: dba@jet.uk (dennis armstrong)
Subject: Re: Executable file format request (again)
Date: 23 Apr 92 15:50:33 GMT

An executable program file (.PRG, .TOS, .TTP) is divided into four segments.
These segments are the file header, program with data field, symbol table,
and relocation data.

file header.
byte # contents
$00,$01 $601A (bra $+1A) branch to program start
$02-$05 Length of the program segment (text)
$06-$09 Length of the data segment (data)
$0A-$0D Length of the additional storage segment (bss)
$0E-$11 Length of the symbol table
$12-$1B 00,Reserved
$1A Program start address

The text, data and bss segments are those segments defined in standard 68000
assemblers.

Each entry in the symbol table is seven words long and contains the name, type
and value of the symbol.
byte contents
$0-$7 symbol name
$8-$9 Symbol type relocatable, global or external
$A-$C Value (address, register number, direct value etc).

The symbol table may be 0 length if the symbols have not been included.

Following the symbol table is the relocation table, this table contains the
distances between the longwords which must be relocated. The first longword
in this table specifies the offset of the first longword to be changed from
the start of the program. After this bytes are used whose value gives the
distance from the current longword to the next longword to be changed. If

the distance is greater than 254, bytes of value 1 will be inserted untill
the distance is less than 255. The first byte to contain 0 indicates the end
of the relocation table.

When the program is loaded into memory the relocation table is no longer
availiable, this means that relocation of a memory image of the program is
not possible (unless of course you write it pc relative!). The memory
image is not the same as the file image.

|>

Almost correct, the text segment starts at 0x1C .
An alternative description is the function below that
reads and relocates text and data:

```
typedef struct {
short magic;
long textLength,
dataLength,
bssLength,
symbolTableLength;
char reserved[10];
} headerType;

/* sizeof(header_type) == 28 */
/* magic == 0x601A */

/* the relocation table follows the symbol table upto the special value
EORELTAB */

typedef struct {
char name[8];
short kind;
long value;
} symbol;

/* special relocation values: */
#define EORELTAB 0
#define EXTENSION 1
```

```
load_and_relocate(fd)
int fd;
{
extern char *lalloc();
headerType header;
long valueToAdd;
char *textAndData;
long currentOffset;
unsigned char relVal;

fread(fd,&header,sizeof(header));
textAndData = lalloc(header.textLength + header.dataLength);
read(fd, textAndData, header.textLength + header.dataLength);

/* the program in the file has absolute addresses as if it */
/* were loaded at address 0, so add the start of the text */
/* to the absolute addresses. */

valueToAdd = (long) textAndData;

/* skip the symbol table */

lseek(fd, header.symbolTableLength, SEEK_CUR);

/* the relocation table starts with a single long which is the */
/* offset of the first address to relocate. The rest of the */
/* table are unsigned char's, offsets from the previous address*/

read(fd, &currentOffset, sizeof(long));
*(long*)(textAndData+currentOffset) += valueToAdd;

read(fd, &relVal, 1);
while (relVal != EORELTAB) {
while (relVal == EXTENSION) {
currentOffset += 254;
read(fd, &relVal, 1);
}
currentOffset += relVal;
*(long*)(textAndData+currentOffset) += valueToAdd;
read(fd, &relVal, 1);
}

free(textAndData); /* :-) */
}
```

From: cse0507@desire.wright.edu
Subject: Re: Executable file format (finally)
Date: 23 Apr 92 05:29:51 GMT

Hmmm...here's some info excerpted from Abacus' disk drives book.

On disk, it's the file header, program with data field, symbol table (if present), and relocation data (if present)
Header first:
2 bytes, = $601a (BRA $1a)

4 bytes, the length of the program segment
4 bytes, length of the data segment
4 bytes, length of the bss
4 bytes, length of the symbol table
10 bytes, reserved, should all be zero (unless...fastload bit? TT RAM?)
Immediately after is the program. "All addresses which the program uses are
set up so that the start of the program is taken as address zero"
The relocation table contains the distances between the longwords which
must be relocated. The first longword specifies the offset of the first
longword needing changed, starting from the beginning of the program. All
subsequent values in the reloc table specify offsets from the previous
value; a linked list of values, if you will. If the next longword needing
relocated is too far (>254) to be expressed properly, the value 1 gets
inserted until the distance is <255.

From: bammi@acae127.cadence.com (Jwahar R. Bammi)
Subject: Re: Executable file format question
Date: Mon, 13 Apr 1992 05:37:39 GMT

Ok here is one for the N'th time, along with the gcc-lib include file:
==========

The format for a .prg, .tos or .ttp file is as Follows (word = 16 bits).
- 16 bit relocatable objects are not supported by Gem Dos.

14 Word Header
Text Segment Image
Data Segement Image
Symbol Table (Optional)
Relocation Info (Optional)

Header Format:
Byte Size(words) Contents
0 1 Contains 601A H Denoting Contiguous
text, data and block storage segments
2 2 Size of Text Segment - Bytes
6 2 Size of Data Segment - Bytes
10 2 Size of Block Storage Segment - Bytes
14 2 Size of Symbol Table - Bytes
18 2 Reserved - Always Zero
22 2 Reserved - Always Zero
(This is supposed to contain the
Begining of the Text Segment and
execution, but execution always begins
at the top of the Text segement, hence 0)
NOTE: In TOS 1.4 or greater these are the program load flags.

26 1 If Zero then Relocation info IS
present, No relocation info otherwise.
Always Zero for Gem Dos.

Symbol Table Format: (this is the DRI format, other formats exist)
Each entry is 7 words.

Byte Size(words) Contents
0 4 Name - zero padded to 8 characters
8 1 Type
10 2 Value

Type Value
defined 8000 H
equated 4000 H
global 2000 H
equated register 1000 H
external reference 800 H
data based reloc. 400 H
text based reloc. 200 H
bss based reloc. 100 H

where:
reloc. == relocatable

A symbol with multiple characteristics has the bits OR'ed in
the type field.
The value field is the value of the symbol (address, register
number, value of an expression or some other value). When the value
field is non-zero AND the type field contains an External Symbol, the
linker interprets the value to be a common region in which the size of
the region is the value in the value field. Multiple such entries may
be present, and the size of common that the linker ultimately decides
on is the one with the greatest value in the value field of the same
symbol.

The nm68 utility provided with the development system can be
used to dump the symbol table.

Relocation Information:
If the last word in the header is Zero the relocation info is
present in the following format: (following symbol table if present)

Byte Size (BYTES) Contents
0 4 Offset from the beginning of the Text
Segment of the first longword needing
relocation.
4 1 Relocation offset byte
5 1 " " "
.....

xx 1 A byte containing Zero terminates

Relocation offset byte - Gives the offset to the Next longword
in the Text Segment to relocate (offset from the First Offset) and so
on. When an offset of Zero is encountered the relocation info
is terminated. The bytes of Relocation offset give succeeding offsets.
(so the smallest legal value is 4 (size of long word)). If a

succeeding offset is greater than 254, then a byte containg One (1)
will be encountered, signifying add 254 to the previous total.

I hope that I explained the above clearly. I guess an example
is appropriate to say what i mean.
Suppose that the first longword to be relocated is at offset
128 from the begining of the text segment. The next one is at offset
132 from the begining. The next is at offset 390 from the begining
of the text segment (ie. 258 bytes from the second longword to be
relocated), Then the relocation info looks like

byte Size(BYTES) Contents
0 4 128
4 1 4
5 1 1 (add 254)
6 1 4 (128 + 4 + 254 + 4 = 390)

2145. Tempus II under MiNT

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-30 16:34:03 UTC
From: d8klojo@dtek.chalmers.se
Message-ID: <11909@chalmers.se>
Source record: 44194

Yes, it's really possible to run Tempus II under MiNT!

I've never believed the people who blame Tempus's crashes under MiNT on the way
Tempus does its window scrolling. Tempus has always been my favorite editor
so, finally, a few weeks ago I started looking for the real problem.

Two hours later the problem had been found and fixed!
Tempus II now runs happily even with a few BGACC-shells on screen.

To patch your Tempus II executable, follow the instructions below (it's easy!).

In the executable file, search for the first occurrence of the word $04a2.
The word directly before this should be $2f38.

The instruction is: move.l $4a2.w,-(a7) $4a2.w = savptr

This is the start of some code that calls the operating system to get the state
of the capslock key. Unfortunately it's done from within an interrupt (the same
one that updates the clock in the corner).
Without MiNT the code works because of some fiddling with the 'savptr' system
variable. I don't remember exactly what's done, but you could look at the code
if you're interrested. ;-)

MiNT crashes when this code has been called a couple of times!

I'm not sure what the problem is, but it can be fixed by changing the $2f38
mentioned above into $602a.
This is a branch instruction that simply skips the offending code.

With this patch, Tempus runs fine under MiNT, but you lose the capslock
indicator. :-(

Editing executable files can be a problem, since normal editors can't handle
the strange characters and long "lines". I usually load the file into some sort
of assembly language debugger, for example DevPac2.
Whatever means you use, you have to make sure that the length of the file you
save after patching is equal to the length of the original file (of course).

There is no guarantee that this patch will work with your version of Tempus,
but it does with the three I've tried it on.

If there's any problem, mail me at the address given below.

>
>Has anyone SUCCESSFULLY created a desk accessory with GCC 2.1 ?
>
>--
>Warwick

If Gcc 2.1 is similar to previous ST versions of gcc, you have to do
some stack fiddling to run an accessory. I did this recently and it
worked, but the following is from memory:

/* gcc init code needs a special stack convention for DA code; the
* following is an excerpt from crtinit.c:
*
* Acc convention:
* user sets _heapbase to bottom of stack + heap area
* sets _stksize to the size of this area
* at startup, sp will be set to top of this area
* (_heapbase + _stksize ) and malloc()'s will happen from heap.
* (note malloc() and *not* Malloc())
*
*/
char myheap[HEAP_SIZ+10];
void *_heapbase = (void *)myheap;
long _stksize = (long)HEAP_SIZ;

...

I hope this helps.

2149. Using vs_color on STe/TT

Newsgroup: comp.sys.atari.st.tech
Date: 1992-05-31 02:34:34 UTC
From: hartlenk@newton.ccs.tuns.ca
Message-ID: <1992May31.023434.17571@newton.ccs.tuns.ca>
Source record: 44199

I have a MEGA ST2 and I need some information on the vs_color() VDI function as it applies to the STe and TT.

On the ST/MEGA vs_color(handle,pen,rgb) is used to set the colour of a drawing pen and rgb is a three element array holding a value 0-1000. Since the ST/MEGA only has a colour palette of 512 (8x8x8) the rgb values passed to vs_color and be 0,142,285,428,571,714,857 and 1000.

My question is: Since the STe/TT have a colour palette of 4096 (16x16x16), what are the sixteen values that vs_color will use?

>worse, Gemini does not pass them out to RUNNER.APP.

This will be fixed in the next Gemini release. Until then, you could
(a) install more RAM :-) or (b) set the environment from within the AUTO
folder (so that GEM programs started with shel_write inherit it).

Ups. That's confusing, I agree. Will be changed in future editions :-)

2152. Re: Setting up GCC 2.1 with gulam ? (How ?)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-01 06:13:27 UTC
From: bammi@acae127.cadence.com
Message-ID: <BAMMI.92Jun13135727@acae127.cadence.com>
Source record: 44022

In article <1992Jun11.181251.11302@oz.plymouth.edu> oddjob@oz.plymouth.edu (Andrew C. Stoffel) writes:
> Can anybody tell me what I should be doing to get gcc up and running ?

you should firstly read the documentation (in the doc/ sub directory the file gcc-st.tex)., and the README files sprinked with various part of the compiler.

then you need to set up your environment variables: (use syntax as appropriate to your shell)

```
setenv GNUINC 'g:\include,e:\include'
setenv GNULIB 'e:\lib,g:\lib'
setenv GCCEXEC e:\bin\gcc-
setenv GXXINC 'e:\g++-inc'
setenv TEMP h: <<<<< note no trailing backslash
```

if you are using gulam, then in gulam.g add
set env_style mw

GNUINC is a comma seperated list of directories where you put the include files for the library.

GXXINC is a comma seperated list of directories where you put the libg++ include files.

GNULIB is a comma seperated list of directories where you put the lib binaries (*.olb and crt0.0 and gcrt0.o)

GCCEXEC is the directory\gcc- (a minus at the end) where you put the compiler executables gcc-cc1.ttp gcc-cpp.ttp. gcc-as.ttp, gcc-ld.ttp and gcc-cc1plus.ttp (this may look like gcc-cc1p.ttp if you dont use UNIXMODE).

TEMP directory for the compiler to use for temporary files. a ramdisk works best for this.

Now to you PATH add the directory where you put gcc.ttp (this may or may not be the same has the directory where you put the other compiler binaries).

that should do it. to check your setup try (in gulam make sure you have env_style set to mw):

```
gcc -v hello.c
```
then try
```
gcc -v -mshort hello.c
```
if you want to try compiling for MiNT and have installed the MiNT libs
```
gcc -v -mint hello.c
```

```
gcc -v -mint -mshort hello.c

and try
gcc -v hello.cc -lg++

to see exactly what the compiler is doing. if you see forward slashes, dont
be alarmed, the libraries handle forward slashes in pathnames even if
UNIXMODE is not set.

cheers,

2153. How to upload to atari.archive?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-01 06:25:49 UTC
From: neuhaus@vier.informatik.uni-kl.de
Message-ID: <neuhaus.707379949@vier>
Source record: 44201

Hello.

I have recently ported the 4.4BSD version of the bourne shell and less
v177 to mint, and have already uploaded them onto our local ftp
server, ftp.uni-kl.de. While ftp'ing from a.a, I noticed that,
despite numerous requests to do so, nobody had uploaded the files. I
wanted to upload them myself, but could not, since the only directory
I found that was world-writeable was atari/new, which, in turn, was
not world-readable. Since I didn't want to overwrite equally-named
files by accident, I did not put the files there.

So my question is: Is there a standard operating procedure by which to
upload files to atari.archive? Please answer by mail.

If you reply, please send mail to neuhaus@informatik.uni-kl.de, not
neuhaus@vier.informatik.uni-kl.de. This is a bug in our news software,
and I'm not sure when we'll get it fixed. Thank you.

Message-ID: <92153.052012JOKHC@CUNYVM.BITNET>
Source record: 44203

I suppose the problem is caused by gemini using an appl_exit(file);
(or whatever) to run runner.app. Gemini exits, telling the desktop to run
runner.app, and runner.app inherits the desktop's enviroment, rather than
Gemini.
Solution? Use an autoboot enviroment setter for any universal enviroment,
then use mupfel.mup for mupfel specific var's.

2156. gulam problem

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-01 09:27:20 UTC
From: beaumont@CompSci.Bristol.AC.UK
Message-ID: <2124@csisles.Bristol.AC.UK>
Source record: 44202

I have noticed that 'if' does not work properly on my version of gulam.
I have the following test.g file...

```
if { -e d:\file }
echo it is there
ef
echo it is not there
endif
```

assuming the file d:\file is actually present on this disk, when I run test.g
the 'if' always evaluates to 0 and fails and the second echo writes to
the screen. The problem seems to be that the whole line is not being read in.
When I change the if line to...

```
if 1 + { -e d:\file } == 2
```

the if always succeeds, regardless of whether d:\file exists or not. But if I
have...

```
if { -e d:\file } + 1 == 2
```

then this always fails. It appears to me that 'if 1 + ...' is read as 'if 1'
and always succeeds whatever file I am testing for (I get the same problem
for -d -f etc).

The version of gulam that I am using starts up with:
beta-test version 1.03.05.05 032588

I have TOS version 1.2. and my 520STFM is upgraded to 2.5 megabytes with
XtraRam Delux.

Can anyone give me any advice, or point me in the direction of a gulam that
works properly.

[...]

I have an AT-SPEED at 8MHz. It works fine, except for harddisk acces. Once every few minutes (using turbo pascal 6.0) a read error occurs. I don't know where the errors are coming from. I suspect that the driver software tries to read through SCSI, without retrying itself. I never have problems like that using TOS. (I use ICDBOOT 5.3.0, and a Quantum drive.)

2158. How to use GDB with GCC 2.1 ?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-01 16:13:09 UTC
From: timm@mpii02017.mpi-sb.mpg.de
Message-ID: <TIMM.92Jun1181309@mpii02017.mpi-sb.mpg.de>
Source record: 44205

```
Hallo,

I tried to debug a C++ Program, that I compiled with the newest version
of GCC 2.1 for the atari with GDB PL 18.
I did the following:

gcc -xc++ -c -g foo1.c
gcc -xc++ -c -g foo2.c
gcc -xc++ -c -g foo.c
gcc -o foo.tos foo.o foo1.o foo2.o -lX -lY -lm -lg++
sym-ld foo.sym c:\gnu\lib\crt0.o foo.o foo1.o foo2.o -lX -lY -lm -lg++ -lgnu

This gave me the TOS executable and the Symbolfile (sym-ld was PL 27).
I was able to run the executable, to run gdb and load the executable and
even start it (with r and c), but when i tried to load the symbol file
(or even the symbolfile alone to gdb), gdb gave an error message like
'Unknown symbol ':' in symtab at position 123' or something similar.

I'd like to know if gdb 2.6 PL 18 is able to debug c++ program compiled
by gcc 2.1 and if i have to use different switches for sym-ld.

( I hope bammi has an answer to this questions :-))

Jan,
Are you using an ms-dos disk cache? That is a definate no-no
for ATSpeed. I've got the 8mhz version and have no problems
with it at all...other than certain hardware-access problems,
like disk caches, which must be avoided...Oh, yeah, I cannot
seem to configure Kermit to work with my mainframe properly,
but that is most likely NOT a problem with ATSpeed (as others
have told me they can use terminal programs on it).

I have used the super charger for about a year. It works fine with most
programs. It occasionally locks up when a program tries to use com1:. You
see, com1 is the mouse, and it just doesn't work well as a modem.

I also (occasionally) get a repeated character at the com port. No idea
why.

The good news: I have successfully coded, compiled and tested C programs
that were to be used for telecommunications in a MS-DOS environment. Hundreds
of users never knew it was compiled on an Atari 1040 STe. :-)

2163. C encryption routine

Date: 1992-06-01 23:44:47 UTC
From: ssw9@aber.ac.uk
Message-ID: <1992Jun1.234447.12891@aber.ac.uk>
Source record: 44213

Greetings,
I am looking for a piece of C source for the ST which performs fast(ish)
DES encryption along the lines of the UNIX crypt() command. Ideally, the routine
should take two parameters, the first being the string to be encrypted, and
the second to be a two character 'key'.

Does anyone have such a routine, or can anyone give me a hint as to where I
could get such a routine or how I could write one myself.

Thanks in advance,

Simon.

2164. Telebit modem + ST problem.

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-02 00:12:44 UTC
From: timg@ccwf.cc.utexas.edu
Message-ID: <73224@ut-emx.uucp>
Source record: 44214

Hi,

I recently acquired an old (1988, but has latest ROMS) Telebit Trailblazer Plus modem that I would like to use to connect at high speed to a similar modem at work (the modem at work has 1988 ROMS). The connection works fine at 2400 baud, but is very jerky at high speed (9600 - 19200). A few lines will blast quickly to the screen, then there will be a long pause, then a few more lines appear very quickly, another pause, ...

The pauses are so long that the total throughput is about the same as at 2400 baud. It looks like a flow control problem, but turning off flow control in Uniterm doesn't help. I also increased the size of Uniterm's buffers, with no effect. The new serialfx program on a.a also had no effect, but I am not sure that it installed itself properly (it seems to run OK from the auto folder, but the cpx module tells me it isn't installed).

I have seen this modem work fine with two telebits connecting two sun workstations, so I suspect something about my ST is messing up the flow of data. Does this problem sound familiar to anyone. I would certainly like to be able to use the full potential of the modem.

Can this be related to the problem that serialfx is supposed to cure? If so, are there any known compatibilities that keep serialfx from working? I tried moving around my TSR's a bit, but was never able to get the cpx to recognize serialfx.

Any help will be appreciated.

Source record: 44215

guess I'm not the only person who had this problem..... the
solution (given to me by Jwar Bammi [sorry :-(, I know I've spelled
it wrong]) is to cat the files together and then un-zoo them.....

Cat'ted together you end up with a 1.4+meg file.....

It would be nice if they where uue'd into smaller pieces instead of
chopping a binary file into that many pieces. The only problems I had
were because of a corrupted piece... so I had to d/l the thing twice.

This is probably a QIC connection. It looks like the tape drive is NOT
an "embedded-SCSI" kind of drive (it would probably have an 'S' suffix
if it were), but instead requires the ICL board to interface it to SCSI.

> the same size as the wider of the cables that goes into the RLL drive.
> However, on the RLL board the only spare socket is the smaller size (so I guess
> I would have to daisy chain the wider cable if I had another RLL drive).

As I understand it, that SCSI-RLL board will have one 34-way connector,
which should be daisy-chained to both the RLL hard drives in parallel
(these are the control signals), and two 20-way connectors, which are
wired individually one to each drive (these are the data signals).

The 34-way to the tape drive will not be the same as the 34-way to the disks.

> Any ideas as to what I've found and whether I could wire it up ????

Possibly. You would need both the tape drive AND the ICL board, and
connect the ICL's SCSI to the SCSI bus in your HD setup. Make sure you
get the terminators correct (only install on the device at each end of
the SCSI bus), and that the SCSI ID's are all different (you probably
know this anyway).

Whether the recently-posted tape software would work, I have no idea,
but I guess there's a good chance it will, provided the ICL board
understands "standard" SCSI, and is not an older SASI-style board.

Hope this helps.

Tony.

In my gulam.g file I regularly use these kinds of tests. Here is a
small portion that has never given me any trouble

if -e o:\gulam.hlp
set sdir o:
ef -e c:\gulam.hlp
set sdir c:
ef
```

```
set sdir a:
endif

if -e o:\rde.ttp
set rdx rde
ef
set rdx rdy
endif

set aux a:
if -d g:\bin
set aux g:
ef -d c:\mwc30\bin
set aux c:\mwc30
endif
```

etc. etc. Note that I do not have the curly brackets {..} that
you have. Perhaps if you removed these your problems would dissappear?
O, I forgot, I also use a machine with TOS 1.2 at present - but have an
STE (at home) where the same gulam.g file also works. The version of
GULAM I use is the latest (version 4.05, I think, from memory).

2171. Command line parameters in C

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-02 14:40:50 UTC
From: hartlenk@newton.ccs.tuns.ca
Message-ID: <1992Jun2.144050.23580@newton.ccs.tuns.ca>
Source record: 44217

I'm having a problem getting command line parameters on my ST. The following program works fine in Turbo C (for the PC), on the HP 9000 at the university. However, it doesn't work with Lattice C v5.06 or Sozobon C v2.0. argv[0] has a null string instead of the path and program name. Sozobon also doesn't handle a quoted parameter such as "This is one parameter" properly, it breaks it into four pieces.

Can anyone tell why this won't work on the ST properly?

```
#include <stdio.h>

int main(argc, argv)
int argc;
char *argv[];
{
int i;

printf("argc = %d\n",argc);

for(i=0;i<argc;i++)
printf("argv[%d]: %s\n",i,argv[i]);

return;
}
```

```

Check out 'Cryptography and Data Security' by Dorothy Denning. It's the
bible of computer-based cryptography and coding theory, so your library
should have a copy. It has a chapter on how DES is implemented.

If you're interested in a more humourous discussion of whether DES is
actually safe or not, check out 'Computer Networks' by Andy Tanenbaum. It's
an interesting read...

> Lattice C v5.06 Sozobon v2.0 argv[0] contains an empty string

This a problem with TOS, not the compilers. TOS doesn't have a standard
way to pass the program name to the program; there are some non-standard
ways of digging it out of the parent's address space, but these will
likely fail on future (multitasking, protected) OSes. Recently, Atari
defined the ARGV standard which lets programs (especially shells) pass
a proper argv[0] to a program. TOS itself won't use this standard tho.

> Sozobon also doesn't handle a quoted parameter such as
> "This is one parameter" properly.

Should it? I've never seen anything in writing that says it should
behave that way. Does MSDOS work like that (I've never tried it)? Does
Unix work like that? I'd be willing to change the next release of HSC
to work like that if there was a clear concensus that that's the right
way to do things and existing programs won't break. (Although, now that
I think about it, under the ARGV standard, that is something that the
caller has to worry about, since the args are pre-parsed in ARGV parm
passing.)

argv[0] is null because it is impossible to determine, in general, what
command line was used to launch a given program on the ST. This is due to the
semantics of the Pexec call, which starts child processes. Some shells put
the name of the executed program into its environment, but if you aren't
running one of those shells...

I'm still on 1.0 (:-( ) but with the impending release of MultiTOS I figured
it is worth hanging on until Atari release it later this year (or next year,
or the year after ....).

Interesting, under MiNT when I tried to do 'F'ollowup in Mercury rn I got
the error 'Illegal argument' and nothing happened. Works fine (as you can
see) without MiNT installed - odd !

You may not be able to use DES - that one takes an 8-byte key.

This is probably a FAQ, so mail replies might be appropriate....
(BTW, where is the FAQ for this group?)

I would like to connect a Microsoft mouse to my 1040 ST. Is this
possible? If so, how? (Rather detailed description preferred; I'm quite
a novice when it comes to techie matters on the ST...)

And while I'm at it: Is it possible to connect a standard PC keyboard
to the ST? Anybody know how?

Thanks!

I don't think it should.

Having the startup code become sensitive to special characters would just
lead to confusion. The ARGV standard provides a way for the parent process
to arrange arguments to its liking, and that's plenty of flexibility.

Of course, we'd all take ARGV a lot more seriously if Atari supported it
with software, not just words.

When I ran that short program on the PC and the HP 9000 the quoted argument was left as one argument so I assumed a problem with Sozobon. Would be nice if quoted arguments were left alone in Sozobon, but others may disagree.

As for the argv[0] problem, I'll resist any temptation to use it in my programs!

Thanks Ian, and everyone else that has replied here or through mail.

2184. Music sources?

Newsgroup: comp.sys.atari.st.tech

I would like to see some sample sources for music players on ST.
C preferable, but this is not a requirement. If somebody can
provide titles of archives from a.a:/atari/music this would be
just great. Unfortunately Index does not indicate a presence
of sources and I do not feel like grabbing everything in sight
just to find out that there is nothing which I would like to see.

Thanks,
Michal Jaegermann

>pause, ...

I use a t2500 on my st, I have found that 19200 will not work that well.
I have had to change alot of the S=registers in the modem to get things to
run smoothly. You will find that 9600 will work better due to the flow control
problem with the st. Make sure you use the manual for the modem, and set up
everything correctly. Try this for starters

AT S50=9 S66=1 This will lock the modem 19200 operation.

Again, try to get the ST flow control fixer to work. It will. I have no
trouble downloading at 19200, but I CANNOT upload at that speed.

Make sure you set the S=Registers correctly, play around with them.

At the CeBIT this year I saw a serial mouse driver sold by
Omikron (I could be wrong about the company). It was intended for
the ST book (for those who don't like the vector pad), but it
seems likely to me that it will run on any ST. They demonstrated
it with a Microsoft mouse.

|> >I welcome any and all information, opinions, factoids
|> >and rumors.
|>
|> [...]

I have had AT-SPEED C16 (16mhz version of AT-SPEED) for about six months, its very fast, if you want to run Windows3/3.01 in VGA MONO on an SM124 it has no problem with that at all, it even runs it at a usable speed. The VGA emulation is a bit unpredictable with most other software that tries to run in it- I have yet to find a PC game which will run in VGA or EGA mode, sometimes you just get a blank screen, other serious type software (NDD and some virus killer utils that run in Graphics Mode give a sort of 'ghosty' picture- not unlike what you see when you load a Degas/Neo lo-res picture to a HiRes screen by mistake!)

Thats the only bad news, but unless you really want to play games- let alone ones for PC's its rock solid. I supports EXtended memory on an ST bigger than 1meg (4MEG ste gives nearly 3meg XMS) and works fine with my ICD SCSI Harddisk, in fact if you get the interleave on the hard disk right (under GEM) the hard disk access times under MSDOS are a might faster than TOS's, sound is a bit of a joke- but then again so is the PC's. with 2MEg+ you can call it as a Desk acc.

Stange Quirks: TC++ crashes at random during a make if it is allowed to use XMS for compilation.

Keyboard repeat seems to ignore MODE.COM so you're stuck with a bit of a slow keyboard.

It is handy being able to call it from a desk acc, but if you can sacrifice the task switching you gain the memory used by the frozen Desktop, and its about 1/3 faster.

Well thats enough waffle- hope this is of use to someone.

Any replies/questions by email as I'm on study leave for exams..

2189. NOTICE :: Emacs 18.58

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-03 21:31:00 UTC
From: skolodzieski@vaxc.stevens-tech.edu
Message-ID: <1992Jun3.163100.1@vaxc.stevens-tech.edu>
Source record: 44235
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hello,

I decided to make this post because of the recent flood of posts
concerning the Emacs 18.57 that I ported late last year. It seems that a
great many people have a very hard time getting it up and running. The major
problems seem to be with termcap entries, environment variables, and UNIXMODE
settings.

I have a MUCH improved emacs 18.58 in beta right now. It has the
folowing improvements over the old emacs:

1. Screen ouput speed is 3x faster. (Really!)
2. The flow control (^s/^q) problem when text was
scrolling has been fixed.
3. External command that are involked from emacs, (like in dired)
are search for along the PATH.
4. A termcap file does nopt have to exist. There is a default termcap
entry compiled in! If a valid termcap file is found and
the TERM environment is set properly, emacs will use the
termcap file. This is especially useful for those who run
second terminals off the ST through the serial port under MiNT.
Personally I have a VT220 attached to my ST :)
5. The "M-x compile" command now works great, it does not need to
spawn a second shell, it writes its output to the correct
buffer, and one can step though the compiler error messages
with "M-x next-error".
6. A generic external process interface is in place, since we are
still single tasking, no external input is allowed, but if
something (like grep/ls/fgrep/gcc, etc...) runs to completion
with no input, then these may be convienently launched with
ouput going to a buffer.

These are the highlights! There are numerous subtle changes also. I will
try to put together some sort of decent TeX documentation on installation
and dumping, then package it up and send it out. Look for it in about 1-2
weeks.

Cheers,
Scott Kolodzieski

2190. A suggestion to Atari ....

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-04 00:54:02 UTC
From: baffoni@aludra.usc.edu
Message-ID: <l2qqdaINNcrm@aludra.usc.edu>
Source record: 44236

Hi,

I realize that occaisionally persons from Atari read this group, so
I am posting this here since I don't have any of your addresses, nor would
I know who to post to if I did.

I have a request regarding your disign of memory connectors for
future Atari products.

After reading throught the Developer docs, the TT logic/hardware
schematic, and talking with the developer support people, I have come to
understand that the TT uses a single 3u connector for TT RAM and two 3U
connectors for ST (64bit) RAM. Now, I have nothing against the TT connector,
but I do have a problem with the STRAM connector.

The ST RAM connectors are designed so that the 64-data lines are on
one connector, and the address/control lines are on the other, along with
numerous tied-to-ground/VCC pins on both. What I would like to suggest is that
on future Atari machines that use a 32/64 bit wide memory model like this,
that they make the 64 bit connectors the same as the 32-bit memory connectors.
In other words, your ST memory will consist of two TT-memory modules, one is
data lines 0-31, the other 32-63, with redundant address and control lines
(if neccessary). By doing this, each connector will have the usual 32 bits
data/address, 2 pins +/- VCC, leaving 30 other pins for control/redundant VCC.
This will allow memory manufacturers to have to produce only ONE memory card
that will work on both ST and TT memory (of course you will have to have two
for ST memory) but the benifits of mass-production should offset costs, and
bring DOWN the costs of TT memory at the same time!

Is there a problem with designing the next generation of Atari machines
in this manner?

-Mike Baffoni

>Is there any easy way do do this?

If you're asking whether two STs can use a single host adapter, I'd say probably not, although I've never tried it. If you're asking whether multiple STs with their own host adapters can share one SCSI bus, the answer is yes, if you're careful. My current setup is two STs and two hard drives on one bus. Works OK as long as you don't try to use the bus from both STs at once.

That reminds me, is there a port of emacs for the ST out there somewhere that take full advantage of MiNT? (Or if someone has a bunch of diffs for the standard distribution, or source with diffs already applied, I guess that's ok too.)

Please respond by e-mail and I'll post a summary back to the newsgroup.

Thanks.

2197. 1.44 M Floppy on Mega STe

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-04 13:55:29 UTC
From: rost@rgb.dec.com
Message-ID: <1992Jun4.135958.5355@ryn.mro4.dec.com>
Source record: 44146
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Now that Mega Stes are available with 1.44 M floppy drives, I have a question that someone who has used one may be able to answer:

I have heard all kinds of stories about compatibility between 720K and 1.44 M floppies on IBM-PCs, mostly that 720K disks formatted on a 1.44M drive may not be readable on a 720K drive. I currently have no dire need for the 1.44M drive (in fact I can save about $100 by buying a Mega with a 720K drive instead) but am thinking of the future. If it will cause compatibility problems with the 720K drive in my 1040 then I'll pass.

Comments?

2202. SCSI-disk transfer rates wanted

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-05 06:46:32 UTC
From: kruel@wpcst1.phys-chemie.uni-wuerzburg.dbp.de
Message-ID: <H.2AQ0UjGZqO6@wpcst1.phys-chemie.uni-wuerzburg.dbp.de>
Source record: 44154

We recently purchased an SCSI adaptor from ICD together with a
Seagate ST 1096N HD and run it on an old Mega ST.

HDRATE gives only 550 kByte/s, whereas the disk itself can transfer as
much as > 1 MByte/s. I remember the ICD adaptor to operate at
700-1100 MByte/s, so what may be wrong ? (Note that the interleave is
1:1).

Anyone out there who can point to tests/rating tables/benchmarks
available ?

I remember there was a fairly extensive test report in the german
magazine 'ST computer' but I can't get it any more.

Thanks in advance, Thomas.

:
: Comments?

I'got an old 520ST (upgraded of course) and when I decided to upgrade
I bought a 1.44M floppydisk (instead of 360K) cause I thought I could
get the FDC to work at 16MHz and this way use 1.44 floppies. Bad luck:
my FDC can't! but anyway I still have a 1.44M floppy and always use it
with 720K disks: I NEVER had any problems with other floppydisks when
exchanging with friends or when reading on any PC !

So no problem, use 1.44M !

I remember changing my interleave from 1:2 to 1:1 and finding the
drive speed to be slower. Try changing to 1:2.

When I ran that short program on the PC and the HP 9000 the quoted argument
was left as one argument so I assumed a problem with Sozobon. Would be nice
if quoted arguments were left alone in Sozobon, but others may disagree.

In my opinion, the problem lies with the Desktop. It should be the
responsibility of the shell to check the quoting of arguments and pass them.

I haven't used one *but* I just read in one of the online magazines (I think it was Atari Explorer On-line but can't remember for sure) that Atari said some Mega STEs have "escaped" with TOS 2.05 and the 1.44 MB drive. The Atari rep (Townsend maybe?) said that TOS 2.05 does NOT format the 1.44 MB disk in a manner compatible with IBM PCs. However, TOS 2.06 will do the job correctly. The summary is that anyone having a Mega STE with the high density drive that wants to interchange disks with an IBM PC compatible MUST have TOS 2.06.

If you don't care about PC compatibility, than apparently TOS 2.05 works fine with 1.44 MB drives on Ataris and is compatible with other Ataris.

I have performed the mod on an English STFM the main difference being
the hertz rating between the two machines and NTSC as opposed to PAL
I can't see any reason it wouldn't work. My setup gets 800x272 in
medium resolution. Great for wordprocessing and manipulating GIF
pictures. Hope this helps. Be daring!!!

This is an absolutely normal value. I just connected a ST1096N to my TT
SCSI port and measured its read performance with SCSI-Tool (32K blocks,
raw read). The result was just below 500 KB/s.

-> The Seagate ST1096N _really_ isn't faster (except when you look for the
'raw' transmission speed of the controller, but who cares?).

> programs with minimal integer only I/O, and I think this is too big.
>

well you first have to indicate what you expect it to be: the
reason i say this is because of the facilities provided by the
library, there is a minimal amount of size overhead. (around 25k) this
obviously has size implication only on very trivial programs. beyond
that since the overhead is fixed its no big deal. what this buys you
is the ability of take majority of pd programs and just compile and
run. (you cant blindly do this of course, but in majority of the cases
you can).

to answer your questions: to link with iio
gcc -o foo foo.c -liio
gcc -mshort -o foo foo.c -liio16 for 16 bit ints

you can bypass a lot of the library overhead by using
#include <minimal.h>
in the main module of your program. when you use minimal.h you cannot
use stdio at all(or anything that refers to a various of type
FILE),signals and many other facilities of the library.

2215. Mac sequencers just do not work with ST+Spectre?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-08 08:01:24 UTC
From: ngse18@castle.ed.ac.uk
Message-ID: <22402@castle.ed.ac.uk>
Source record: 44163
Cross-posted to: rec.music.synth,comp.sys.atari.st.tech

I run an Atari ST with the Spectre Mac emulator; I plan to move to a real Mac platform in time, and am looking to upgrade my cheap/PD Atari sequencing software. I previously posted requesting information from anyone who has tried using Mac MIDI software with Spectre, and on Mac sequencers in general. I received no responses, so here's my experience to date:

A visit to Soho Soundhouse resulted in recommendations for Encore and Cubase and I came away with demo copies of each. Attempts to run them on my ST/Spectre combination failed: Encore loaded and functioned as a score editor, but wouldn't even drive the serial interface (Spectre doesn't appear to know anything about the Atari's MIDI ports). Cubase refused to load, saying there was insufficient memory available - it needs about 800k on a real Mac.

On the basis of somewhat limited evidence, I'm reduced to the conclusion that Mac-type MIDI is impossible on the ST/Spectre combination. Anyone disagree? [GBS sell the Megatalk board for the Mega STE which offers this capability, but I understand that it's not available for the ST models]

Russ

2216. help req'd: mint and mgr with tcsh and elvis

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-08 12:18:35 UTC
From: beaumont@CompSci.Bristol.AC.UK
Message-ID: <2134@csisles.Bristol.AC.UK>
Source record: 44164

My system: I am using a 2.5Mb atari stfm (TOS 1.2) with two floppy drives

3 Questions (and apologies if the answers to these are on a FAQ list
somewhere. I don't have such a list).

1. Can someone tell me if it is possible to run mgr and mint with just
two floppy drives on a 2.5Mb atari stfm (TOS 1.2)

I tried to run mgr and it ran but when I tried to open a window I get the
error message "can't get a ptty". The manual for mgr says...

* - can't get a ptty
* make sure all of /dev/[tp]ty[pq]? are owned by root, mode 666
* and all programs referenced with the "shell" option in the
* startup file exist and are executable

There are no pty devices in my U:/dev/ directory.
Do I need to create these, and how do I do it?
Or, is the problem that I don't have enough memory to create pty's. I have
the system det up with a: and b: as floppy drives and d: as a 720K ram disk.

The documentation with mgr and mint don't seem to provide any pointers to
solve this problem.

2. After I can open windows, I'd like to have tcsh running in a
window. Can I do this by 'setenv SHELL a:\bin\tcsh.prg' in my
mint.cnf?

3. The final question is, I have already set up mgr to run tcsh and
this works. I am using elvis as my editor, and I try to do '!}fmt' to
format a paragraph (the format program, fmt.ttp, is in my path in
d:/bin) but all I get is a very brief error message flashing into (and
out of) the status line at the bottom of the screen. I can't read the
message it is too quick, but it looks like the same message if I try to
use a program which is not in my path. So I suspect that the elvis can't get
the PATH variable, or tries to use /dev/d/bin instead of d:\bin. Anyone have
any advice on this one?

I tried setting the vector to a routine that just incremented
a variable, and that didn't seem to work. So I disasembled
the code that's normally at the vector, and included that
PLUS the line that incremented the variable, and that didn't work.

> I'd be interested to know if anybody can explain why I seemed to loose

>
> ANY AND ALL INFORMATION IS GREATLY APPRECIATED!
>
>_John_

I tried to do something very similar with HBL interrupts, but I couldn't get the palette changes to occur on the same line all the time - when I moved the mouse around the colours would drift down the screen as if some HBIs were being missed out (it was a lot worse than +/- 3 scan lines).
Remember that the default HBL routine switches IPL 2 off, so you will have to set up your routine first then enable it (but then you would probably do that anyway).
I'd be interested to know if anybody can explain why I seemed to loose HBLs (I reset the colours in the VBL - was this the problem?). Also is there a hardware register which tells you which part of the screen is currently being scanned?

2222. vs_color VDI question

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-08 16:22:33 UTC
From: hartlenk@newton.ccs.tuns.ca
Message-ID: <1992Jun8.162233.140@newton.ccs.tuns.ca>
Source record: 44166

SOMEONE PLEASE HELP!!!

I was wondering if someone could answer a quick question
reguarding the STe/TT computers (I have an MEGA ST2)?

I posted this before but I'll ask again. I was wondering if
anyone knows any details about how the vs_color VDI function
works on the new STe/TT computers?

vs_color(int handle, int pen, int rgb[3]);

vs_color requires that the rgb array be loaded with
appropriate colour values, the ST the values are:

(from Computes! Tech. Ref. Vol I. VDI Functions, page 73)

requested actual hardware register
value value colour level
----
0 - 70 0 0
71 - 213 142 1
214 - 356 285 2
357 - 499 428 3
500 - 642 571 4
643 - 785 714 5
786 - 928 857 6
929 and up 1000 7

This allows for 8x8x8=512 different colours. However, the
STe/TT can have 16x16x16=4096 different colours. Does
someone know what the corresponding table for STe/TT looks
like? Is backwards compatiblity taken care of by the STe/TT?

2223. Re: HBLs, Has anyone been successful in using them?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-08 18:22:33 UTC
From: bpat@cs.mcgill.ca
Message-ID: <1992Jun8.182233.16768@cs.mcgill.ca>
Source record: 44173

Yup, well not the HBL interrupt, but something which does it better.

First, about the HBL interrupt itself: For some reason, it seems to close
turn itself off immediatly after it occurs, therefore only being done once
for each page (Gets put back on at VBL)
Besides, using it is slow, and not too sure. (The sT will not run it if
a higher interupt is working, and IPL 2 is *LOW*)

So, here is a much better approach:

Timer B is hooked up to the HBL signal !!!

If put in mode 0, it will be decremented by one at every HBL !!!
It is then *VERY* easy to count screen lines.

I don't want ot give too much detail about it now, as I do not have the
manuals with me, and would most certainly make huge mistakes.
So I'll tell you what : On wednesday or friday (Whenever I log on again),
I'll post a program I worked on, which puts a rotating color effect in the
menu bar. It uses VBL and Timer-B-HBL (Not HBL interrupt).
It's in assembly, but well commented, so there should be no probelms.

If there are any other things that need details, I'll always be reading this
newsgroup, so please, let no one hesitate to ask away, however silly it might
seem. If more people get to learn the ST's "hidden" stuff, then we'll all be
getting better software, no ?

Patrick.

2224. Re: vs_color VDI question

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-08 18:33:31 UTC
From: bpat@cs.mcgill.ca
Message-ID: <1992Jun8.183331.17018@cs.mcgill.ca>
Source record: 44174

VDI is made so as to allow more powerful computers to use it. Whereas the ST take a range value of 0-7 (Or 0-15 for the STe / Mega STe and TT), VDI takes 0-1000. So all you need, is to make a conversion, with 0 = 0 and 1000 = 15. Here, 8 is in the middle, and so should get 500 (Or therabout, as Atari people may have rounded up some numbers and it may not have come up right)

Patrick Betremieux.

2225. Keyboards question

Hello all,
My wife has a Mega-STE; however, she hates the keyboard and
would rather use her Mega-ST's keyboard. Does anyone know if the
keyboards are compatable? She would prefer not to send any of the
components up in smoke.

Thanks!
Matt

>
>-> The Seagate ST1096N _really_ isn't faster (except when you look for the
>'raw' transmission speed of the controller, but who cares?).

Not only that, but remember, HDRATE tests the "real-world" speed of
a drive, not its maximum speed. If you were to do a sequential-track read
off of the Seagate, I am SURE that you would indeed get > 1MB/s. However,
it will never load that fast for you unless you a) defragment your drive after
deletions (with additions), b) make sure that any programs you load are located
sequentially on the hard drive. This is why one uses HDRATE. You don't use
your HD in a "perfect" manner as above, so HDRATE exemplifies "typical" if not
pessimistic HD by a user. That just goes to show you how BU**-kicking fast the
Quantum LPS drives are, that they can take this abuse and still get around
800-1.2k MB/s - and this is its AVERAGE speed.

However, these are SCSI-1 drives connected to SCSI-1 controllers. To
really see some statistics (as in > 4MB/s SUSTAINED) you will need to get a
machine with SCSI-2 controller connected to a SCSI-2 drive. BTW, does anyone
know if a SCSI-2 controller can push the envelope of a SCSI-1 drive? I mean
does it still get the same performance as a SCSI-1 controller (or worse?)
or will it outperform the SCSI-1 controller?

>Newsletters & Manual.

Maybe it's a cultural thing, but I find that little is clearly stated in
Gadgets' Newsletters or Manual; were English not my first language, I would
probably have a very hard time. As regards MIDI, the only statement I've
ever been able to find is on page 3 of Newsletter 5, which, as an afterthought
to the sales pitch for the Megatalk board says:
" ... for the first time ever, Mac MIDI programs now work with Spectre
GCR, with standard Mac MIDI interfaces."
which carries the implication that Spectre *may* work with some interfaces -
the later discussion talks of the Apple and Passport products. These boxes
really contain very little: they perform a voltage to current loop conversion
and a serial speed adjustment. Surely we have an adequate pool of knowledge
in this forum to work out what is needed to make this kit function?

No, it's rather like Unix. You can run several Tos prgs in real
multitasking (preemptive) but you can run only 1 Gem prg.
For several Prgs, wait until MultiTos or get MultiGEM or Mag!X !

I look forward to being able to do this properly, and assembler is fine!

>seem. If more people get to learn the ST's "hidden" stuff, then we'll all be
>getting better software, no ?

I've been working on a "Motif-like" user interface "widget set" for about 2 years now, that's looking pretty good. Unfortunately I've had to develop my own mouse, keyboard, and MIDI drivers, which took a while. Most of the reason that it's taken me so long, is that since I rewrote the keyboard handlers, I can't use a debugger! (I contemplated writing my own, and still might)

It only runs in medium res, and makes abundant use of the 4 colors, but I want to expand it so different areas of the screen can have other colors.

John

^^^^^^
Why not check out the Atari demo version of Cubase. I believe it
is the same or slightly newer than the Mac version, and will give
you an alternative to your cheap pd sequencer.
You should have no trouble selling an ST/Cubase combination to
another musician, as it's a very popular combo.

You might just be in luck! I repacked the GCC 2.1 files in order that
they fit on 720k floppies. I'll have to check patchlevels but:

-rw-r--r-- 1 ralph 1338928 Apr 16 17:57 gcc21bin.zoo

became

-rw-r--r-- 1 ralph 454534 Apr 4 07:16 gcc21bn1.zoo
-rw-r--r-- 1 ralph 515020 Apr 8 00:26 gcc21bn2.zoo

and

-rw-r--r-- 1 ralph 5042851 Apr 16 18:40 gcc21src.zoo

became

-rw-r--r-- 1 ralph 695810 Apr 5 07:19 gcc21sr1.zoo
-rw-r--r-- 1 ralph 715787 Apr 5 04:51 gcc21sr2.zoo
-rw-r--r-- 1 ralph 721968 Apr 2 02:21 gcc21sr3.zoo
-rw-r--r-- 1 ralph 697407 Apr 5 04:09 gcc21sr4.zoo
-rw-r--r-- 1 ralph 534391 Apr 5 04:15 gcc21sr5.zoo

Checking patchlevels gives:

zoo -print gcc21sr1.zoo ./PatchLev.h

********
./PatchLev.h
********
#define PatchLevel "1"

/*
* the Patch Level above is to identify the version
* of the all the files in this directory. given the above
* number i can pull up the correct version of any individual
* file in this directory. in all communications i will appreciate
* very much if you can quote this number.
*
* $Author: bammi $
*/

Should I upload these to a.a?

It's just a new AES with limited multitasking capabilities (quite
similar to MultiGEM 2: upto 16 prgs and accs at the same time but
not preemptive multitasking). In fact it is written by the authors
of KAOS 1.4.2 but is not distributed the same way: this time it is
a normal Tos extension with auto-boot start-up. As it is a rewritten
AES, some compatibility issues are not excluded !!

See test in a german magazine (Atari Journal or ST Computer).

The ICD Advantage series host adaptors say that they support the SCSI-2
command set. So if I use a drive which supports SCSI-2 (Maxtor LXT 200s)
is SCSI-2 actually being used in this setup, or does the ICD still
use SCSI-1?

```
Hello,

In sozobon133 I tried to declarate the following (or like it):

1 typedef struct x {
2 int data;
3 x *next;
4 } xtype;

this did give the error:
'}' missing on line 4 and syntax error on line 4.
looking into a C book I changed it into (and inbetweenies of the two)

1 struct x {
2 int data;
3 struct *x;
4 };
5
6 typedef struct x xtype;

well, same error's. By the way I did include stddef (and malloc), must
I include something else or is something different with sozobon133?
Don't tell me it only has array's..

Please email (bert@cs.vu.nl)

Bert.

>Mega 4 ST + ICD advantage ST plus + ST1480N (423MB): HDRATE says 1320kb/s

Wow, if I upgrade from TOS 1.0 to TOS 1.4 (or 2.X), can I expect speeds like this? I have heard that 1.4 is faster, but I didn't expect this much increase. Right now, HDRATE reports about 550 on my machine, which is:

4M 520 + ICD advantage ST plus + Quantum ProDrive 80s.

...

You need a combination of the two.

typedef struct x {
int data;
struct x *next; /* next is a pointer to the type "struct x" */
} xtype;

There is nothing wrong or different about sozobon, this is run of the mill
C syntax.

Is it *absolutely* impossible to use GCC and only one meg? I have a hard drive, I know that's essential... but I'm only a beginner at C. Would I be able to compile small programs with that kind of setup? Or should I just forget about it? Thanks in advance.

> ST/Spectre combination failed:

You're right, Mac MIDI software doesn't run under Spectre without Megatalk,
I don't know if it does with Megatalk. You seem fairly confused about MIDI
software, though. Why on earth would you try to run Cubase under a mac
emulator on an ST, when Cubase 3.0 is fully available for the ST? No
emulators, no extra boards, etc. Also you mentioned Encore, this is available
for the ST. The best sequencer in the world for any platform is in many
musicians' opinion Notator 3.1, which runs ONLY on the ST. Other top
MIDI software for the native ST mode would include KCS Omega and Copyist DTP.
It's beyond me why you would want to run midi software under Spectre.

Of course the STE and TT VDI allows to set 16*16*16 different colors. But I don't see why the information which exact values are returned would be of any particular interest for an application program. And don't forget, that with many third-party graphics cards (and the presumably the Falcon 030) you'll get even larger palettes.

>use SCSI-1?

I think it is still using SCSI-1, and that it is compatible with SCSI-2 so you don't have to be so careful about which drive you get, so long as it is SCSI. This is just my best guess. Especially considering that for the ICD to be fully SCSI-2 compliant, it would mean that the Atari ACSI port would have to support the 16-bit (I believe) data path, which it doesn't, and the increase in data-throughput - which I doubt (even if it does DMA data from the ACSI port). That would be a neat chip in the ol' "my computer is better than yours" war with the Macs - "Yeah, we could have had SCSI-2 back in '85, we just didn't wanna...and besides, somebody had to make a SCSI-2 drive before we could use it anyway - and that's _built in_ to ours...What, you mean the new Quadra 950 still uses SCSI-1? What a lark ..." :)

Well, here's to hoping the new line of computers has SCSI-2 ...

Forget it. I tried 2 Megs and couldn't even compile the zoo sources, whose largest file was about 80kB. But an upgrade of your memory would be cheep if you own a STE. Note this. I did so (4MB) and was happy.

Yeah -- remember to set the processor interrupt level to <2.

> I'd be interested to know if anybody can explain why I seemed to loose
>HBLs (I reset the colours in the VBL - was this the problem?). Also is
>there a hardware register which tells you which part of the screen is

Yes there is -- I don't know off-hand where it is, but it is documented in the Abacus books and other, more reliable, Atari internals texts.

Since HBL is a low priority interrupt, any other higher priority interrupt that is being serviced at the time HBL is fired may mask it. Since _all_ of the other interrupting devices in the ST have a higher interrupt priority, this can be a significant problem!

Source record: 44045
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hi,
I have an atari TT machine, one of the first with the daughter
board containing the 32 mhz 68030 on top of the mother board.
I would like to change the internal SCSI disk from 50 Meg to
a Quantum 120 Meg drive. Then connect the 50 meg SCSI drive to the
TT via the external SCSI bus.

(i) Has anybody tried upgrading the internal drive in the
TT machine. Will the Hard Disk driver support this type of
drive.

(ii) I have heard that there could be problems in using
two 'High Performance' SCSI drives on this model of TT,
when both are connected via the SCSI bus, any body
tried this !!

(iii) What sort of cables are needed, and where can I
get them from.

Thanks in advance

Andy

As I recall, High-Speed has adequate access to GEMDOS calls for you to use the Pexec command. It's gemdos call (hex) 4b. Just look up in the GEMDOS section of your built-in help for anything like that.

Noooo!
The code that's executed as standard lifts the processor interrupt level to greater than 2, disabling the HBL interrupt! If you really want to use the HBL vector, do the following:

0) Go supervisor mode
1) Change the vector to point to your HBL code
2) Set the processor interrupt level to <2 (0 is fine)
3) Go back to user mode

I've been playing with MultiTOS recently and it's really quite groovy. It's amazing that it works at all! Essentially, Atari have licensed MiNT, made some changes, and re-implemented AES, VDI and the Desktop on top of MiNT.

The only problems I've had are with programs that do any of the following
1) Grab all memory (though this can be worked around using MiNT's ability to limit the memory given to a process at start up)
2) Fail to use WIND_UPDATE to lock the screen when they draw dialogue boxes or anything else, because they assume they're the only program on the system. (Unfortunately, this covers a _lot_ of software!)

I saw something about this in the Glentop book (Concise Atari guide or something like that...). Even if you use the counter connected to the HBL interupt (at IPL 6) rather than HBL interupt itself the timing will still be too unstable - especially when you move the mouse. The culprits are the MIDI/IKBD and system clock interupts. The recomended procedure for getting stable palette changes mid screen they recommended to

(1) Catch the MIDI/IKBD and lower the IPL to 5 before calling the original routine.
(2) Block the system timer all together.

Note that you can't do quite the same trick with the system timer (ie just lower the IPL) because the two TOS routines are mutually non-reentrant - I found this out the hard way.

A trick I use (for MIDI input not HBL but it should work for HBL) is catch the MIDI/IKBD and mask both interupts in the MFP chip mask reg before lowering the IPL & calling the TOS routine and ditto for the system clock. This seems to avoid the TOS reentrancy problem without losing track of the time.

Steven

2258. Memory upgrades....

Newsgroup: comp.sys.atari.st.tech

I have been working on a similar problem using interrupts and am having no luck also.
I am trying to read a graphics tablet through the serial port and use the value obtained to reposition the mouse position.
When I do this in a foreground loop everything is ok, but when I move the same code to the mouse or timer interrupt vectors the machine crashes.

Does anyone have any suggestions on what needs to be done so that reading the RS232 can be performed in the background this way?

Thanks.

>For the record I'm using TOS 1.2 with Neodesk 3.?.
^^^^^^^

Sounds like that may be your problem. When you start your machine,
do you use something like FolderXXX.prg in your Auto folder? If not, you are
probably running into the 40-folder bug. If you have access to a bbs or can
ftp to Atari.Archive, then just about anyone should have the FolderXXX program
(BTW, the XXX represent numbers - you change the name to add more folders that
can be opened).

Or, you might consider gettting a newer version of TOS. 1.4 is good,
but you might be better off getting the TEC board with TOS 2.06 and all the
goodies that come with having the new TOS. What goodies you may ask? Well..
Lots - I don't think that I should waste bandwidth on what should be in the
FAQ.
Speaking of which, isn't time for FAQ to do the rounds again?

Hope that helps...

She does not like the 'feel' of the keyboard. She has to type harder to
get the keys to register. The key that causes the most problems is
the shift key.

Yeah. You need to logically remove them, but you don't have to do it physically. If you cut the power lines to the chips, then they won't be using power or getting in the way, but if you should need to take out your memory upgrade for any reason, it would not be a big deal to just resolder the chip power leads and Presto, you have your old memory back (Of course you have to be real careful when resoldering the leads as you could blow a chip if it gets too hot...).

If you don't want to just remove the power leads, then yes, you have to remove the chips (if only for power considerations alone).

Message-ID: <1992Jun11.054237.431@usenet.ins.cwru.edu>
Source record: 44060

I'm looking for a cable that from the STe's monitor port will connect to the 9-pin connector on the SC1435 AND have an RCA composite video connector. The closest I've been able to come is a male monitor plug that has the pins needed for composite but not for RGB with H- and V-sync.

Joppa has a couple composite cables listed in their catalogue but they have no discriptions.

Anyone seen one of these or be willing to put one together for cash, eh?

2268. Programming the Blitter

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-11 06:21:39 UTC
From: vicb@clark.edu
Message-ID: <1992Jun11.062139.12361@clark.edu>
Source record: 44063

Could someone please tell me of a good source of information on programming the blitter chip? I am not too familiar with the STe's internals, most of my programming has been done on the UNIX at school. Is the blitter accessible (easily) with C? A book title or magazine article would be great. I have the text file blit.arc from the umich.edu archive but would like to get more before I actually give it a stab myself. Any C libraries out there that would be of help? I will be using Heat-n-Serve C (aka Sozobon 1.33i).

Much appreciation,
Victor Bruhn
vicb@clark.edu

This should be no problem. BTW, there are a lot of drivers on the market.

> (ii) I have heard that there could be problems in using
> two 'High Performance' SCSI drives on this model of TT,
> when both are connected via the SCSI bus, any body

It seems to me that I have the same machine version. I use a Fujitsu 2624S
as internal drive (1.7 MB/s transfer rate) without any problems.

> (iii) What sort of cables are needed, and where can I
> get them from.
Simply use the old cable and switch the drives. That's all there is to do.

Rather than write your own debugger, couldn't you just intercept the TOS keyboard calls and handle them with you own routines?

|>
|> It only runs in medium res, and makes abundant use of the 4 colors, but
|> I want to expand it so different areas of the screen can have other

|>

If you're building your GUI from the bare metal up you could also try implementing amiga style interlace for 640x400 in 4 colours. I think all you have to do is keep 2 medium res screens - one for odd scanlines & one for even - and flip between them using the VBI.

By going for 640x400 it is easier to convert any displays to mono (and if you ever write for the pro MIDI market you _have_ to support mono).

BTW back in january you mentioned a 61 note piano keyboard demo - did you ever release this? If so where can I get a copy?

Changing the TOS version won't speed up BIOS calls, so the raw
transmission speed won't change. But the change in GEMDOS performance _is_
worth the upgrade.

If you get my init(8) package from Atari.archive plus a shell or two you can
have a Unix-look-alike machine with the serial port acting just line a
terminal port on a Unix box.

>Second, the UNIXMODE setting doesn't seem to be documented anywhere, how
>does one use it, and how does it work?

MiNT doesn't use UNIXMODE, instead you can get the minix filesystem device
driver off Ataari.archive, format a partition using minit (I think that's
what it's called) and use it. The Minix filesystem is a Uniix V7 filesystem
look-alike so you can have filenames up to 15 characters long, upper and
lower case, full access permissions etc.

You also can just set the select signals of each bank to inactive:
RAS,CASH and CASL (that are used for the new, bigger RAM bank) are
to be interrupted (on the old, smaller RAM bank side) and set to 5V.

So, for each signal (RAS0,RAS1,CAS1H,CAS1L,CAS0H,CAS0L):

before:

```
------
MMU <-----| |--------------------> OLD RAM BANK
------
resistor
```

after:

```
------
MMU <-----| |-------| 5V ----> OLD RAM BANK
------ |
resistor |
|
```

```
|
|
V

NEW RAM BANK

You might also try to use the HSync interrupt (I think this is wired to one of the MFP's inputs, so it is a vector interrupt). I find this much easier to use than HBL.

I don't know where you will find those incompatible STE-TOS but the M-STE I upgraded at our local dealer (Media Markt) last month had 1.44MB drives and the 'compatibles' (Highscreen, Profex ... with DOS 5.0) in which I tested the HD disks from the M-STE didn't complain

|>
|> If you don't care about PC compatibility, than apparently TOS 2.05 works

The times ATARI is totally incompatible (with the drives) is over.

I tried getting 640x800 on my monochrome monitor this way, but it was way
too flickery to bother with. In colour the it would be even worse (25Hz
instead of 35).
I have a friend with an amiga and apparently to need a long persistance
monitor for interlace modes to be usable, and these are generally mono only.

: : >removed for the sake of keeping the machine cooler. Any comments?
: : > Thanks,
: : > Jonathan
: : > krakover@spot.colorado.edu
: :
: :
: : Yeah. You need to logically remove them, but you don't have to do it
: : physically. If you cut the power lines to the chips, then they won't be
: : using power or getting in the way, but if you should need to take out your
: : memory upgrade for any reason, it would not be a big deal to just resolder
: : the chip power leads and Presto, you have your old memory back (Of course
: : you have to be real careful when resoldering the leads as you could blow a
: : chip if it gets too hot...).
: :
: : If you don't want to just remove the power leads, then yes, you have
: : to remove the chips (if only for power considerations alone).
: :
: : -Mike
:
:
: You also can just set the select signals of each bank to inactive:
: RAS,CASH and CASL (that are used for the new, bigger RAM bank) are
: to be interrupted (on the old, smaller RAM bank side) and set to 5V.
:
: So, for each signal (RAS0,RAS1,CAS1H,CAS1L,CAS0H,CAS0L):
:
:
:
: before:
:
: ------
: MMU <-----| |--------------------> OLD RAM BANK
: ------
: resistor
:
```

```

2289. File selector / menu race condition?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-11 16:54:55 UTC
From: saj@chinet.chi.il.us
Message-ID: <1992Jun11.165455.1366@chinet.chi.il.us>
Source record: 44087

Using the old unimproved GEM file selector under TOS 1.2, it appears that if I move the mouse pointer into the menu area after selecting a file but before the selection is processed, I can drop the menu. This happens with several plausible arrangements of wind_update() calls in the vicinity. Is this a problem other people have seen? Is there a ONE TRUE WAY to avoid it? I hate playing around too much with wind_update() arrangements because mistakes generally require re-booting.

Related point: mouse clicks on the file selector sometimes seem to result in mouse button events being sent to my application with my application's own window handle attached. Common occurrence? Any approved way to filter them out? I'm thinking of ignoring mouse button events that share the same message with redraw events--I don't think that combination arises naturally from my application, and I would expect it to happen from the file selector dropping stuff through.
Steve saj@chinet.chi.il.us

Hi Steven,

>Rather than write your own debugger, couldn't you just intercept the TOS
>keyboard calls and handle them with you own routines?

Perhaps, but I don't know the underlying details... If I suspect some
particular portion of my code is wrong, I can bring back the temporary
keyboard handler just before that section of code, and then I can use
the debugger. This is very time consuming, but does work...

>
>If you're building your GUI from the bare metal up you could also try

>
>By going for 640x400 it is easier to convert any displays to mono (and
>if you ever write for the pro MIDI market you _have_ to support mono).
>

I'm not sure what you mean about the Amiga interlaced mode, and how I
can get twice the resolution in the Y dimension by swapping 2 screens.
For now, I'm just developing this software for myself, but I know it
would be senseless to ignore monochrome systems if I want to make any
money on this!

>BTW back in january you mentioned a 61 note piano keyboard demo -
>did you ever release this? If so where can I get a copy?

Actually, my main program right now has a 61-key keyboard, and realtime
slider display of VCF, Oscillator, Pitch, and Channel Pressure. I want
to beef it up a little before I put in on the net though...

I wanted to get this color changing stuff licked, so I could use different
colors in the keyboard display, than what's used for the other parts of
the screen...

2291. SVGA graphics boards for the TT

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-11 17:46:11 UTC
From: <>
Message-ID: <bnell.708284771@ferrari>
Source record: 44081
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have a couple questions concerning graphics boards for the TT. I know of one made by gribnif and the reSolution board. I also have heard of the Matrix(?) boards from Germany but haven't been able to find a number or an address for them (If anybody knows of one, please let me know). I have also heard of some really expensive boards which are totally out of my price range (<$1000). If anyone knows of any decent boards that I haven't mentioned, please let me know about them. If I get enough info I will post my results later.

My second question is about adapting an IBM SVGA board to the TT. Don't say this is impossible, because nothing is impossible, just extremely difficult :-). The only problem with this is that I don't know anything about the EISA/ISA specs (anyone out there know?). I don't see why this wouldn't be possible, difficult, but possible. So any help would be greatly appreciated.

I think this would be very important to TT owners who want better graphics for a decent price. (You can get SVGA boards for the IBM for ~$100 as opposed to ~$500 or more for the TT). So, let me know!

Thanks
Bill

2292. Setting up GCC 2.1 with gulam ? (How ?)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-11 18:12:51 UTC
From: oddjob@oz.plymouth.edu
Message-ID: <1992Jun11.181251.11302@oz.plymouth.edu>
Source record: 44082

Can anybody tell me what I should be doing to get gcc up and running ?
I've tried it with both gulam and MiNT (running ksh.tos as the shell)
and it doesn't work..... does anyone have a .g file for gulam that
sets up the correct environmental variables for gcc ?

And --> where can I get a make that works with it ? I got one off of
a.a but with MiNT I get "can't find mmacros" and with gulam I get "not
enough memory"

What am I doing wrong ? I DO have enough memory :-). With NOTHING
running (that is -> MiNT or gulam) I have 3700K free.....

I really want to go to gcc.....

Also, is there a resource builder that works with TOS 2.05 ? The one I
have from MWC crashes every so often at random..... (i learned to
save OFTEN :-).

Any help would be appreciated.... thanx.

2293. Help replacing DMA chip

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-11 19:21:08 UTC
From: aacampbell@miavx2.ham.muohio.edu
Message-ID: <1992Jun11.152108.792@miavx2.ham.muohio.edu>
Source record: 43997

This is somewhat... well REALLY embarassing, but a while ago I got the crazy idea of applying about 6 volts DC (500 MA) to different pins on my cartrige port on my early model 520 ST just to see if any values changed in memory or for some other really goofy reason like that. Yes... I know it was S T U P I D! and I found that out the hard way.

After I was through "playing" I reset the computer, the floppy drive light came on for a few seconds and I got the message "Disk drive error, Insert disk or check cable... (or something like that). This now happens every time I turn it on.

I had a friend hook up his hard drive to my computer and his hard drive never even flickers. He mentioned that I probably toasted the DMA chip.

Now I am starting to miss my Atari and was wondering if anybody had any ideas. If it is the DMA chip, is it an easy job to unsolder and solder the chip? Where would I get a DMA chip for this early model 520 ST? Anybody know the cost of this?

Thanks in advance,

Andrew aacampbell@miavx2.ham.muohio.edu
(older, wiser?, owner of toasted ST)

2294. gcc 2.1 vs gcc 1.40

Newsgroup: comp.sys.atari.st.tech

Hello,

recently I got gcc2.1. I noticed the binaries are considerably larger
than 1.40. As memory always is scare on our ataries, I wonder if it is
worthwhile to use 2.1 instead of 1.40. Does anyone know about:

- real memory consumtion of 2.1 vs. 1.40?
- quality of produced executables (speed) of 2.1 vs. 1.40?
- compile time speed of 2.1 vs. 1.40?

2295. Getting AHDI and SUPBOOT to cooperate

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-11 20:52:47 UTC
From: bigham@hercules.acpub.duke.edu
Message-ID: <3304@news.duke.edu>
Source record: 44084

Having recently purchased a Mega STe with an internal hard drive :-D,
I'm in the process of transferring stuff from my Supra external HD to
the internal drive. Only problem is, I can't get both drives working at
once. The Supra drive was formatted with Supra's utilities and requires
SUPBOOT.PRG, whereas the internal drive was formatted with Atari's
utilities and requires AHDI.PRG; neither program, unfortunately, expects
any other hard drive handlers to be around, and so they don't cooperate
(I tried, for instance, booting from the internal drive and running
SUPBOOT to get at the Supra drive, but then both drives thought they
owned the C: partition -- not a pretty sight). As it stands now, to get
anything off the Supra drive, I have to reboot with the Supra utilities
floppy, copy the desired files onto another floppy, and re-reboot from the
internal drive.

What I want to know is if there is any trick, short of reformatting the
Supra drive with the Atari utilities, to get AHDI to recognize and deal
sanely with the Supra drive? Editing the boot sector, perhaps?
Ideally, what I'd like to do is have both drives up at once, so I can
determine by actual use patterns what I really need from the Supra drive
and junk the best by reformatting.

As far as I know, accessories need a special startup code
to be linked with! I.e. free ALL Main memory they can.

To the orig. poster:
Are you shure you used the correct startup code?

I don't use GCC up to now so I don't know if there is any
at all!

Be carefull doing this. Most DRAMs are specified such that if you hold
RAS high for more than 4milliseconds (and I bet you leave your machine on
for longer than that!) then their operation is *NOT* specified *AT ALL*.
Also most DRAMs require 8 wake up cycles after switching on before they
operate correctly. I have measured (I used to work in component test)
currents *much* larger than normal operating supply current under these
conditions on several different brands of DRAM.

Moral: leave RAS connected, just perform the mod on the CAS lines only.
My machine operates quite satisfactorily with just such a modification.

NB1: If you fry your machine modifying it, then *YOU* fried it!
NB2: Opinions expressed are my own and in no way relate to my employer.

> shell which I used (see "ms.zoo" on A.A's gnustuff/tos/othergnu) as CLI.

The problem doesn't seem to be the total program length, but the length of the biggest function in the program. GCC keeps the whole function in memory while compiling it.

For compiling GCC 1.40's c-parse_tab.c (the Bisoned C grammar), I need more than 3 MB (have to remove the RAM disk when I do it). Luckily, I don't do this very often ...

I have the same problem. However when I access the sound control CPX, the noise suddenly diminishes (~30 db!). I figure that when you exit the CPX, all the sound control registers are sent to the circuits which control them. Latching must drain a capacitor (or something along these lines..) which allows the noise to be filtered. Somebody will come up with an auto-folder fix (or even TOS...nah) someday.

hi net world. our lab recently got 2 new TT030's. we have an "older" TT030
we bought about 18 months ago. the tech manual reports this "older" unit
runs the 68030 at 16 MHz, while the owner's manuals for the new ones say
the 68030 clocks at 32 MHz. is this true?

so we moved all our applications from the older TT onto the others. all our
favorite software and development tools work fine, but we can't get anything
to work with the modem ports or serial ports. Atari's VT52 emulator,
Stalker and Uniterm all refuse to function, and changing the modem parameters
in the desktop does nothing to help.

is there some bug in the OS shipped with these new machines that gives
the modem ports a problem? any other suggestions?

thanks in advance
vic spicer

>- quality of produced executables (speed) of 2.1 vs. 1.40?
>- compile time speed of 2.1 vs. 1.40?

One of reasons that executables of gcc 2.1 are bigger are that you
are getting two (or three - depending on compile options) compilers
in one. Namely C, C++ and Objective-C. If you are dabbling in C++
then combined compiler is actually quite a bit smaller than two
separate beasts. There are also differences in a generated code
and optimizer is more aggresive. I do not have any quantitative
measurements (anybody with a set of numbers?). If this is worth
for you - I do not know. 1.40 is pretty capable compiler on its
own and in this moment more stable than 2.1 (or 2.2 in a few days)
but this will change and you are hard pressed to run into problem
areas.

>
>What are the main differences between SCSI-1 and SCSI-2?

Disclaimer: I am in now way to be considered a SCSI expert (or a
clean expert for that matter :), BUT, these differences I am reasonably
sure of:

1) SCSI-1 has a max transfer rate of 4MB/s. SCSI-2 has a burst transfer rate
of 10MB/s and a sustained rate of 8MB/s.

2) SCSI-1 can only talk to one drive at a time. SCSI-2 can talk to multiple
drives at a time (but they must all get the same data stream, meaning they
can "mirror" the data).

3) SCSI-1 has an 8bit data path. SCSI-2 has a 16bit data path.

4) SCSI-2 protocol (I believe) is a superset of the SCSI-1 protocol - it has
additional commands, probably related to the new features.

5) SCSI-2 contollers and drives are more expensive. :(

I think that is about it. Can anyone else add to the list?

2310. FSfirst bug?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-12 17:15:42 UTC
From: yannikos@vmars.tuwien.ac.at
Message-ID: <1992Jun12.171542.21214@email.tuwien.ac.at>
Source record: 44004

I recently found out that one of my programs (Naughty Unpacker) doesn't work correctly on TOS 1.2 and 1.6, because FSfirst doesn't seem to find a file which exists in the current directory, if called with the filename only (as returned from the fileselector) and it should be in the current directory (on the current drive). I call FSfirst with attrib = 0 (since it's a 'normal') file. This is particularly strange, because as far as I know, TOS 1.6 and 1.4 have the same GEMDOS version number (0.15?), and it works fine on TOS 1.4...

Has anyone experienced the same problem?

thanks in advance,

Marinos Yannikos

>Don't suppose anyone's got C sources for the maths library function "gamma"
>have they? ST binary will do.

there is a piece of code in "Numerical Recipes in C" (pg 168) which give the natural log of gamma(z) (based on Lanczos approximation):

```
#include <math.h>

double gammln(double z)
{
/* gammln() returns ln(gamma(z)) for z > 0. full accuracy for z > 1.
for 0 < z < 1, the reflection formula can be used:

gamma(1-z) = pi/(gamma(z)*sin(pi*z)) = (pi*z)/(gamma(1+z)*sin(pi*z))

gammln is implemented rather than gamma since the latter can overflow
easily. thus gamma(z) = exp(gammln(z)) (i think...).
*/
double x, tmp,ser;
static double cof[6] = {76.18009173,-86.50532033,24.01409822,-1.231739516,
0.120858003e-2,-0.536382e-5};
int j;

x = z-1.0;
tmp = x+5.5;
tmp -= (x+0.5)*log(tmp);
ser = 1.0;
for (j=0; j<5; j++) {
x += 1.0;
ser += cof[j]/x;
}
return (-tmp+log(2.50662827465*ser));
}
```

i can't vouch for accuracy in this. there is no error checking either (eg gamma(0), etc).

u might also look at the gnu C math library (pml) or the 4.3BSD release (tahoe or reno, whichever is the PD version).

>rick wittstruck
>witts@hoss.unl.edu
>Univ. of Nebraska-Lincoln

If you write a .PRG it doesn't have to use windows and menu bars - just switch the cursor on and clear the screen using the VT52 codes and it will look exactly like a .TOS program except for the mouse pointer. Note that you must hide the mouse before writing anything to the screen (including clearing it). If it really must be TOS program (perhaps because you want to run it from the \AUTO folder to save memory) then you do indeed have to put a sprite on the screen yourself. The current position and button state can be obtained from linea structures. To draw the cursor it is probably best to intercept mouse messages using the XBIOS call (Ikbdvec or similar).
Mail me if you don't have suitable reference books to look the details up.

2314. Help with Quantum 210s HD and WINCAP

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-12 20:13:32 UTC
From: snoret@egon.unx.sas.com
Message-ID: <Bpr1IL.KCI@unx.sas.com>
Source record: 44010

I just got the Atari Hard Drive Utilities from the binaries newsgroup and need some help. The header for the HDX v5.00 states that for SCSI drives like the Quantum 210s (I have a Quantum 210s Prodrive that I haven't installed yet), WINCAP is now only required for ST506/412 drives or SCSI drives connected through ACSI that HDX cannot determine through the "mode sense" commands, such as a Quantum 210s, due to the fact that the "Inquire Capacity" command uses all 8 bits of the command byte.

Here is my delimma: I have an _OLD_ 1040STfm, TOS 1.0, and a Supra 20MB hard drive (one of the original Supra Drives for the ST). I know I need to get TOS1.4. Is there any way I can swap the Quantum for the Miniscribe in the Supra case? I've tried it (half-heartedly) and got it to format a couple of partitions, but never got it working quite right.

I want to be able to format the Quantum so that about 1/3 is for my ST, and 2/3 for Spectre/Mac. Does anyone have a working WINCAP entry for a Quantum Prodrive 210s? Would you email me a copy?

I am _NOT_ a hard drive expert. Only recently have I began tinkering with mine, since I need more MegaBytes.

Any and all help will be greatly appreciated!!

Thanks in advance,

Rick

I think the assertion that fsel_input and fsel_exinput do an implicit
wind_update(BEG_UPDATE) is wrong. If you don't wind_update before you
call the file selector box, button/mouse events are sometimes also sent
to the active application.

I ran into a problem once with Fsfirst/Fsnext (I've got TOS 1.(0)2 BTW)
Using the default DTA didn't work reliably so I had to set my own.

From: bigham@acpub.duke.edu
Message-ID: <3330@news.duke.edu>
Source record: 44011

Problem solved; both drives are now on line. The problem wasn't what everyone thought it was, but it was close. Almost everyone who replied (thanks to all of you, BTW) suggested that both drives were set to the same SCSI ID; I'd already corrected that (when both drives had the same ID, neither worked!), setting the Supra drive to ID 2 (the internal drive defaults to ID 0). On a lark, I reset the Supra drive to ID 1. Jackpot! I am a bit perplexed, though. Apparently, AHDI stops scanning the bus when it finds an unoccupied ID; this seems counterintuitive. Is this deliberate?

No, I don
't have any TT RAM for sale, but I do have TT FAST RAM in my TT.
It is the GE SOFT board. It uses SIMM (expandable to 32MEGS FAST RAM). Right now I installed four 4megs simms in it (16megs) and it work great. The price is a lot cheap than the ATARI ram board. The GE SOFT board is available from ATY COMPUTER (510-482-3775) for $450 or so. Get the SIMM from somewhere else, it's cheaper.

Hello - I agree! I am using my Mega STE(German with UK TOS 2.06) and an
American Mega keyboard, it works fine - all ST keyboards are compatible as long
as the TOS agrees with the keyboard layout. If they don,t - as in my case - the
only problem is to remap the keyboard, which is done with a simple keyedit
program. Hope this is some help to someone!

Neither does the Mac!!

>Cubase refused to load, saying there was insufficient memory available -
>it needs about 800k on a real Mac.

It only needs 350K on a REAL ST!

>On the basis of somewhat limited evidence, I'm reduced to the conclusion
>that Mac-type MIDI is impossible on the ST/Spectre combination. Anyone
>disagree? [GBS sell the Megatalk board for the Mega STE which offers this
>capability, but I understand that it's not available for the ST models]

I see little point in trying to use Spectre with software ported to the Mac
from the ST in the first place and then moaning that is doesn't work properly!
In the Atari ST you have one of the best music application computers in the
world and you want to run Mac software on it???

I think you should look at the REAL capability of the ST before you try to run
emulation sofware on it. I use the ST professionaly with both Cubase and
Notator and have yet to find any major bug or fault. No offence intended and I
hope you get your Mac, if only to allow you to find out what an expensive and
no standard medium it is!
Best of luck!

The TOS version (for HDRATE) does not matter as they directly drive the DMA port with software, it does not use BIOS. Most of this speed comes from the quick seagate drive. My maxtor 213S gets about 1120Kb/s with tos 1.4. and a 8Mhz Mega 4.

Is there anyway to overscan an SM124 Atari monochrome monitor? Is it actually possible on an SM124 for the electron gun to scan the borders, or is it limited to inside the borders?

Conan.Ford@Debug.cuc.ab.ca

2328. Real-Time interprocess communication (MiNT)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-13 19:33:07 UTC
From: hrs@aber.ac.uk
Message-ID: <1992Jun13.193307.18377@aber.ac.uk>
Source record: 44024

Dear Netters,

I'm interested in controlling a program from another program in the same manner as DDE in Windows, i.e. real-time control. I read in the MiNT docs that Mint has various ways of allowing programs to talk to other resident programs, i.e Signals, Fifos (pipes), shared memory, Rendezvous and Semaphores. With such a multitude of options I'm not sure which method I should be using. I was wondering if anyone has any good advice on this matter?

thanks
Herb

2329. gulam gem command under MiNT/tcsh

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-13 21:31:08 UTC
From: rosenkra@convex.com
Message-ID: <1992Jun13.213108.14512@convex.com>
Source record: 44025

i know this question has been asked, but i have not seen an answer.

i am using MiNT 0.94 and tcsh 6.0.0.2 (the latest port). how can gem programs (particularly uniterm) be run from the shell (tcsh in this case)? i have tried writing a shell to start uniterm, but uniterm starts then immediately exits with bus error (PC=0 is what MiNT sez). shortly after this, the system locks up, needing a reboot.

basically, i do:

```
od = Pdomain(-1) get old domain
Pdomain(0) TOS domain
appl_init() init appl
graf_handle() get phys handle
v_opnvwk(&hndl) open virtual workstation
Cconws("\33f") cursor off
v_show_c(hndl,0) mouse on

system("uniterm.prg") start uniterm, wait for it to end

v_hide_c(hndl) mouse off
Cconws("\33e") cursor on
v_clsvwk(hndl) close workstation
appl_exit end appl
Pdomain(od) reset old domain
exit(status) exit with status from system()
```

i compile this with gcc 1.40 with the MiNT libs at PL 19.

what have i missed? does someone have some code for this? would someone (bammi,apratt) pls post the portion of gulam which does this?

i did not see anything in the tcsh docs to indicate that there was a 'gem' command.

other than that, tcsh is really nice (as is MiNT). i'd hate to have to exit tcsh every time i wanted to run a gem program, nor do i want to run an alternate desktop as a solution to this problem. and i certainly don't have the time to disassemble gulam to find out how this is done.

thanx...

-bill

>>
>> Thanks in advance.
>What TOS version are you running? If I remember correctly one version had
>that problem.

I have TOS 2.06 in a MEGA STe. At the moment I am working on the assumption
that this is not a TOS bug, but a feature. That is, I assume I am doing
something wrong.. The desktop itself uses this function, so I would
assume that the behavior of evnt_multi() is as expected, at least for the
desktop. Moreover, other programs do not have the problem.

Until now I have not received the definite answer. One person suggested
that I would get a small program 'clikfix' to repair the bug, but I would
like to solve this problem within my program. Two others have suggested that
evnt_multi() sends spurious scrolling events, and that I should check for
mouse button down or other events arriving at the same time. I have not
tried that until now, perhaps it works...

>call the file selector box, button/mouse events are sometimes also sent
>to the active application.
>
What I actually have, at present, is
```
wind_update(BEG_UPDATE);
.............
fsel_input();
.............
wind_update(END_UPDATE);
```

So I guess the question can be rephrased as "Under what circumstances, if any,
is it normal for fsel_input() to permit an otherwise-locked-out menu to drop?
If this behavior is strictly TOS 1.2-and-earlier, I won't bother with it;
likewise if it's eliminated with fsel_exinput(). But as I keep telling people
(until they stick a rag in my mouth), I'm working on a program to be used in
a social situation, on borrowed hardware, by people who are drinking. Confusing
behavior has to be avoided.

Warning: I just looked at my code. I think that's what it looks like, and I
think that's what I meant to write. I've been known to miss seeing simpler
things, though.

>
The word I got a while back was that you can give any number of consecutive
wind_update(BEG_UPDATE) calls, and the condition will be cancelled by one
wind_update(END_UPDATE) call. I was told that the behavior from a
wind_update(END_UPDATE) call when the screen was not in the BEG_UPDATE mode
was not guaranteed, and should be avoided. I personally use a wrapper
which counts how many times I've asked for BEG_UPDATE and END_UPDATE, and
calls wind_update only when the count increases to 1 or drops to 0.

^^^^^^
I think this is your problem. The MiNT libraries use the "official" Atari ARGV= way of passing arguments. They use the approved way of inidicating this (putting a 127 as the "length" byte of the command line in the basepage). However, some programs don't like this. I would particularly expect this to be true of programs written in Pascal (e.g. uniterm) since Pascal uses strings with a length byte, just like the command line, and hence no doubt expects the length byte to be accurate.

Try using Pexec(0, "uniterm.prg", "\0", 0L) instead and see what happens.

> i did not see anything in the tcsh docs to indicate that there was a 'gem'
> command.

There isn't. I thought about adding one, but decided that an external 'gem' command would be better (since it could be replaced... it's not clear yet how gem programs are best launched from CLI's under MultiTOS). I never got around to writing one, though... if you can get yours working, please post it!

I would think that the problem is with the TOS version you have. Like I said, the noise exists on my machine at boot-up. However, I tried it again (through my stereo), and the noise seems to drop off at boot-up just as the GEM desktop pops up. So it seems obvious that there's a couple lines of TOS code that take care of the problem.

Get 3.06 (and a high density drive) or wait for Multi-TOS. That should take care of the problem.

> memory, Rendezvous and Semaphores.

Assuming that both programs are aware of the IPC mechanism, you could use any of these methods; which one is best depends upon exactly what kind of control you need to exert, and how much data needs to be exchanged. Also, do you mean "real-time control" in the strict technical sense? If so, you should be aware that MiNT is not a real time operating system (your program can be pre-empted at times when it might not want to be, so no minimum time for response to events can be guaranteed).

Fifos are the most general method of IPC, and the ones that I would recommend using in "normal" circumstances. For very short messages where synchonization between sender and receiver is desired, the Pmsg system call provides for message sending with rendezvous, and may be convenient. The other IPC mechanisms are less generally useful; signals are very crude, semaphores don't pass much information (they're usful mainly for controlling access to shared data structures), and shared memory is (at present) possible only between programs that share a child-parent relationship.

(1) Gulam is not an operating system. It is a command line interpreter (CLI). It will work on any ST.
(2) MiNT is a TOS compatible multitasking OS (actually, it extends TOS to add multitasking). It will work on any ST, but 1 meg of memory and a hard disk are needed to make it really useful. It can run 1 GEM program and any number of TOS/TTP programs at the same time. A CLI (such as tcsh, bash, or gulam, although gulam doesn't know about MiNT's features) is recommended for using MiNT, although you can make do with the desktop and a supplied accessory.
(3) Both programs are freely available (e.g. from atari.archive). Why don't you get them and try them out?

Hope so.

I think that this topic was covered by J. Resnike in one of his first articles
about wind_update() in ST MAGAZINE.

I think that the author of Turbo Ass had disassembled wind_update() and found
that BEG_ incremented a counter and END_ decremented the counter _and_ checked
for underflow.

I would agree with this, however I would add that you should also rename
tcsh.ttp to tcsh.prg as well. I seem to remember gulam having problems
with "gem" commands if it was not launched from the desktop as a "prg".

And do post if you get something working.

This is how I would convert this code...

If you have any problems with it, just e-mail me.

(I'm not sure I got it right, because I'm an Amiga assembly programmer, and
the directives are different in my assembler than they are in ST assemblers)
(ie .globl_tapebios (this code) = xdef _tapebios (Amiga))

```
;
; tapebind.cpp definitions for the library.
; With these it is now compatible with 16 bit integers
;
#ifdef __MSHORT__
.globl_tapebios

.text
.even

_tapebios:
lea 20(sp),a0
; 4 bytes for ret addr + 16 for parameters
movem.l d2/a2,-(sp)
; save registers that TOS clobbers
move.l -(a0),-(sp)
move.l -(a0),-(sp)
move.l -(a0),-(sp)
move.l -(a0),-(sp)
trap #10
add.l #16,sp
movem.l (sp)+,d2/a2
rts
#else
.globl_trap_10_wwll

_trap_10_wwll:
movem.l d2/a2,-(sp)
move.l 28(sp),a1
move.l 24(sp),a0
move.l 20(sp),d1
move.l 16(sp),d0
move.l a1,-(sp)
move.l a0,-(sp)
move.w d1,-(sp)
move.w d0,-(sp)
trap #10
add.l #12,sp
```

```
movem.l (sp)+,d2/a2
rts
#endif
```

Nested BEG_UPDATEs are a bad idea. Under MultiTOS, calling wind_update
(BEG_UPDATE) is an attempt to acquire a semaphore for locking the screen.
Once you have the semaphore, your process is scheduled and you can write to
the screen. You should call wind_update(END_UPDATE) as soon as possible to
allow other AES applications to write to the screen.

Attempting to relock the semaphore (that you already own) will probably
result in deadlock. I say probably because I've not tried it yet!

This looks like output from a compiler, right? The @ seems to be there to
tell the assembler that what went before was a register name...

2346. Setting LUN of Atari SH205 disk

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-15 01:17:23 UTC
From: jmw@lad.med.utas.edu.au
Message-ID: <jmw.708571043@lad>
Source record: 43943

Apologies if you have seen this before, but I have reasons to suspect it
didn't get out the first time it was posted. Text of original message
follows:

Help! I have just added a new SCSI drive to my system, using an ICD adaptor.
Now I want to set the LUN on my SH205 drive so it can be used as well.
The manual only mentions changing the DIP switches, but there is
nothing to indicate which of the jumpers on the board changes the LUN.

Can anyone tell me exactly which jumpers/switches need to be
changed, and what to?

Thanks,

Hi,
I'm trying to write a fractal program that can do 3072 colors/screen (STE), and I'm not quite sure how to implement the palette switch after each scanline. Could someone please tell me where I can get info on this subject?

Thanks.

>I would agree with this, however I would add that you should also rename
>tcsh.ttp to tcsh.prg as well. I seem to remember gulam having problems
>with "gem" commands if it was not launched from the desktop as a "prg".

my tcsh is tcsh.prg.

ahem...i am writing this note from a terminal session via Uniterm running under tcsh. scott and eric were right on: using Pexec things work.

i will clean up the code and post it here and upload to a.a sometime this week. i am not sure whether to call it "gem" or "rungem" or "rgem" or "rg". "gem" will conflict with the gem.prg that starts the desktop. i think i will call it "rg" for no good reason (other than it is short to type).

i'll post both src and prg. nothing fancy since tcsh will allow aliasing for something like:

alias trm 'pushd e:\local\uniterm; rg uniterm.prg; popd'

which is basically what i used with gulam. i think the .rsc needs to be in either $cwd or $PATH. since i don't normally have this in my path, i am really not going to worry about an ultra-general implementation.

farewell, gulam. you served me well...

>University of Western Ontario

You're right I don't mean real-time control in the strict sense. What I mean't was a core program which hovers around in the background waiting for commands from another program eg a shell. What fired me up was a Windows application we have at work which understands all about neural networks. The program itself however is 'dumb' to the outside world and the only way to talk to it and get it to do things is by DDE. This allows a user to write their own command shell (eg using visual basic) which makes it very flexible. This started me thinking that I could do the same trick using MiNT. I shall try using Fifos. I've not yet tried programming with MiNT. I use the Lattice v5 compiler. I'm not 100% sure what to do what I assume I just write the program, link with the MiNT libs and run under MiNT? I've not actually come across anyone who has actully spelled this out. Perhaps in already writen down in the docs.

Thanks for the adice
Herb

[more stuff deleted]

Actually, I think the a0@- is meant to be interpreted (sic) as -(a0).
This instruction seems to be part of a sequence which copies a chunk of
memory onto the stack.

You're not stupid. For the same reason little frogs get cut up in biology class, you need to occasionally open and kill a computer (Well, ethics would demand you to kill it first, and then open it, but I always perform vivisection on my hardware... :-), namely, to fully understand how things work. Personally, I fried my sixth computer some time ago (for the record: a ZX81, a ZX Spectrum 48, a ZX Spectrum 128 (hey, that one's still alive...), and three ST's.)

>After I was through "playing" I reset the computer, the floppy

>520 ST? Anybody know the cost of this?

Well, if you're lucky, you won't have to solder anything. Soldering is dangerous. I always end up with more mess than I started with. In some models, many chips are socketed. In all the ST's I opened, including an old 520 (without the drive built in!) the DMA chip (and the Shifter, and the Sound chip, and the CPU, and the ROMS, and the MMU, and the GLUE) were socketed. Now, if a chip is socketed it's very easy to replace it. I bet some surgeons out there wished humans were built like that.

I heard that a new DMA chip costs about 50-60$, so you'd better be sure if it is really that chip. What you can do is dive in some garbage cans and open up some thrown-away ST's. Plenty of good parts in there.

Message-ID: <1992Jun15.174540.24573@cs.mcgill.ca>
Source record: 43956

```
This is, from what i've heard, the new format Motorola suggested for the
opcodes (I like the old one better if you ask me.)

An@- is -(An)
An@+ is (An)+
An@(16) is 16(An)
An@(Rn:X) is (An,Rn.X)
An@(16,Rn:X) is 16(An,Rn.X)

There is no more "." between the opcode and the size (As movel, not move.l)

you must specify size (No more move for move.w)

The rest should be the same as before.

Notice that An@- and An@+ suffice as there cannot be (An)- nor +(An) anyways.

Patrick BETREMIEUX
```

2355. rg posted to atari.archive (run gem)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-15 17:47:00 UTC
From: rosenkra@convex.com
Message-ID: <1992Jun15.174700.2607@convex.com>
Source record: 43954

i uploaded this to atari.archive so it should appear shortly. here is the readme file. for those who can't wait, you CAN get this before it shows up in the newitems dir. just cd atari/new (you won't be able to get a dir list) but you can retrieve the file if u know its name. in this case, the file is: rg10.zoo. contains src, manpage, and executable.

far from perfect, but it works...

-bill

---

rg 1.0 (92/06/15)
---

rg is a little program designed to make it possible to execute GEM programs from shells which do not have a "gem" command. I wrote it for tcsh since that is what I want to use from now on.

Compiled with GNU C 1.40 with MiNT libraries at PL 19. Tested under MiNT 0.94 with tcsh 6.00.02 (esmith, circa 92/06/01). Never tested under TOS alone or with other shells.

Typically, I just need the following alias to start uniterm (rg's sole use on my system so far):

alias trm 'pushd e:\local\uniterm; rg uniterm.prg; popd'

This works fine for me. See todo for missing features (bugs?). Also read manpage.

Enjoy...

>format to get byond about 2/3 of the way before it gives an error. I thought
>the above fix may be the solution. Can anyone out there verify this or help
>me out?
> Thanks in advance.

That may be the problem, although the problem may also be that you don't have
TOS 2.06. Maybe your dealer can let you try out a set of chips before you buy.

I have an old Mega STE and the 1.44meg drive upgrade doesn't work. :^(I'm
in need of an address line trace and a new PAL which I'm waiting for. I did
the 'power supply' fix and it didn't work. The screw you need to remove is
in the middle of the PS and you have to insulate the connection with some
electrical tape or non-conductive (??) material; in short, it's a bitch to do.
(Hey, and I actually sound like I know what I'm doing. hehehe) I took the
screw out and I can't wait to put it back in. (Hey, no "screw's loose" jokes,
all right? :^) I have some problems with formatting disks with the screw out;
problems that I didn't have before.

To make sure you have a 1.44meg drive, open up the flap on the opening of the
drive and look on the right side. There should be a pin, similar to the
opposite side, that checks for the HD hole in the disks. If there's no pin,
you have a 720K drive.

Hi, netters,

I have been ST-ing since 1985. I switchet to PC some years now.
But those years Dave Small did make quite an impact on the
ST world (the father of the GCR mac emulator).

His name does not show up among the usenet postings too often.

Whatever happened to Dave Small?

(Just wondering...)

You have to use a AES function (graf_mouse) which means you have to
have done a 'appl_init' call first. Or you have to use VDI (v_show_c)
which means you have to open a workstation first.

No other way possible!

From: mintha@geog.ubc.ca
Message-ID: <1992Jun16.005616.2940@unixg.ubc.ca>
Source record: 43962

I have been attempting to install GCC 2.1 using all the suggestions
that have been posted, etc. However it still won't work. When I
try to compile it proceeds fine until it gets to the linking step, then
it complains that it can't find the symbol split_mem referenced from
malloc.o and sbrk.o. Can anyone tell me what I am missing, I think
I have all the latest versions of all the libraries.

Thanxs, Jim

P.S. I finally found UNIXMODE.DOC on a european site somewhere, I still
can't find it at atari.archive (its not in gnustuff/tos/doc directory) if
anyone else wants it, mail me, and I'll send it to you.

I just got the new binary of Emacs 18.57 that was recently uploaded to atari.archive (by JJK I believe) I works great, and is much faster but is there a way to get the arrow keys to work with it? (Apart from modifying the source and recompiling :)

Jim

P.S. I have some elisp code that will remap the backspace and delete keys so that the backspace, will do a backspace, but you don't lose the C-h functions. Email me if your interested.

>drive and look on the right side. There should be a pin, similar to the
>opposite side, that checks for the HD hole in the disks. If there's no pin,
>you have a 720K drive.
Out of curiosity I did that.... & (SURPRISE!!!) I think I have the
1.44 meg drive....

on each side of the drive there is a pin in a sort of
horse-shoe shaped piece of metal. If you (CAREFULLY!!) take a flat
bladed screwdriver and press DOWN (again, CAREFULLY, NOT TOO HARD!!!)
both pins will go down a little.

But what good is that with TOS 2.05 ? Is there any way to format the
things ? I tried but only got 726K & a CPX I have that formats
floppies choked on it when I tried to format in HD.

Someone mentioned being able to format HD floppies using TOS 2.05.

Is there a way of checking for the existence of the AJAX chip ? Such
as a memory location ? The sysinfo.prg program I have crashes on my
Mega STe, is there any program that works on it that performs a
similar function ?

Any answers to my questions would be appreciated.. :-).

>Someone mentioned being able to format HD floppies using TOS 2.05.
>

Well, I just recently got my MegaSTe, and it has Tos 2.05 AND
a 1.44 drive in it. I did the 'power supply fix', which for the
record is simply a lot of screw removing... BUT be careful of some
of them blue capacitors(?) under the power supply, I almost bent one
a bit too muc when trying to put the Power Supply back in its position!
Anyways.... it now formats and reads in high density mode just fine!
I have only formatted from the desktop. Which CPX allows you to format
at HD? I'll look for it. From the desktop is you high density option
greyed out? If it is , I think you have to flip a dip switch if
if you indeed have a HD drive to let the computer know its possible.

As I said my machine is less than a week old, so I am just getting
comfortable with it from my old Mega4. But it DOES have 2.05 and DOES
have a 1.44 meg drive, and AFTER the power supply fix, it has no problems
(yet!) with 1.44 disks.
If there's anything else you'd like me to check i would be glad to help!

JK> You may not be able to use DES - that one takes an 8-byte key.

You can always pad the key to 8 bytes (or repeat it a couple of times).
However I don't think it is a good idea to use 2 character keys. It is just too
simple to do an exhaustive key search.

Hi
I am trying to upgrade the disk drive in my TT from 720 K to
1.44 Meg. I have managed to get TOS 3.06, but the every helpfull
Atari UK are unable to supply me with the new disk controller
chip that is needed 'AJAX' I think.

Anybody know of a Source in Europe ??

Apart from replacing the drive, the floppy controller chip and
upgrading TOS to 3.06 what else must I do.

Thanks in advance

Andy

2367. Hard Disk Project

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-16 12:43:47 UTC
From: ralph@laas.fr
Message-ID: <RALPH.92Jun16144347@orion.laas.fr>
Source record: 43969
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

I currently have an Atari SH204 disk attached to my Mega 4 ST. I have been thinking about a do-it-yourself hard disk project since I have access to some used hard drives. First of all, I would like to have some more information on these drives, since they come with only a defective sector list. They are:

1) Quantum Q540, series 05, 15-50470 rev. A, copy. Quantum 1984. This disk apparently has 480 cyls, 8 heads, and 16 sectors/track. The precompensation cyl. is 256 and the landing zone is 643. Apparently, its unformatted size is 40 Mb and formatted it is 31.4 Mb and it's average access time is 45 ms. The interface is ST412/ST506.

2) Fujitsu Part No. B03B-4805-B003A#N2, rev. B 9, date 1986-4 This disk comes from a Sun-3 shoebox so it might be a Fujitsu M2243AS. The latter is 86 Mb raw, 70.8 Mb formatted.

I would very much appreciate information such as no. tracks/cyl., no. cyls, and no. sectors/track, data transfer rate, mean access time, interleaving, power consumption, etc. Also, what the various jumpers on the card might signify.

The Fujitsu disk also comes with an Adaptec ACB-4000 controller. I suppose that this would convert the disk's native format (ST506 I believe) to SCSI.

I was thinking of putting both disks in an XT style case, together with the Adaptec controller. Is the controller any good for an ST? Can this controller handle two disks? Both seem to be ST506 drives.

What are the pitfalls of such a project?

Another solution would be to use the Fujitsu drive directly in my SH204. I suppose that this might work quite easily. How much power does an SH204 power supply actually supply? The Fujitsu's rating is +12V, 22W and +5V, 8w.

Pleas reply by e-mail, if at all possible, and I'll summarize if there's any interest in such a homebrew.

Thanks a lot folks.

>
This is the way the gnu assembler wants its input:
sp@- means -(sp) (perdecrement)
sp@+ means (sp)+ (postinc)
sp@(20) means 20(sp) (indirect with displacement)

Here is one possibility. This script was written with a specific and
limited purpose of translating an output of gcc into Motorola syntax.
It DOES NOT handle all possible valid inputs. On the other hand is
definitely faster then g2m and needs "only" awk instead of perl.
Have hacking fun extending it. I will leave posting of g2m for
Jwahar. :-)

Dave is still busily creating goodies for the Atari community via his company, Gadgets By Small. His latest is a 68030 accelerator for the Mega ST and of course, they still sell as many Spectre GCRs as they can build. He told me this weekend that since it was released, the GCR has never been out of backorder status. He does check in on the Internet, but infrequently.

I'm not sure that the MiNT library compiles with Lattice (it may need a bit of tweaking). If you don't want to do this, you can just

```
#include <osbind.h>
#include <mintbind.h>
```

and make MiNT kernel calls directly. The MiNT manual pages describe the kernel calls available in <mintbind.h>.

Can anyone explain how to make GCC 2.1 produce smaller executables on the Atari? How, for example, do I use the "integer only" libraries iio.olb, and will this decrease the size of the executable programs I create? All of my executables are about 30-32 K for even small programs with minimal integer only I/O, and I think this is too big.

>which means you have to open a workstation first.

>No other way possible!

Bzzzzzzt.

Use the XBIOS call Kbdvecs() call (or whatever - can't remember) to get
a pointer to the IKBDVECS struct, then change the mousevec in that
structure to point to your own routine which draws a sprite on the
screen, etc. I can't remember the exact method for processing the
mouse packet, but that's how I did it in Graphical GNUchessi - which
has its sources included. It works on all machines I know of (The mouse
change thing anyway, Graphical GNUchess only works on Colour 1M+ machines).

Don't forget to set that pointer back once you've finished, or else you're
just ASKING for a crash.

I'm not sure how this will port to MultiTOS, but that's a problem for the
designers of MultiTOS. Perhaps each application will need it's own KBDVECS
table. It works from MiNT, but again, I don't even know what you *expect*
two such processes to do when running in the background!

Oh, note that the old version of osbind.h (that with gcc 1....) had a slight
bug in the Kbdvecs() macro - the return type was bogus. The whole file is
greatly improved now.

2379. Mega STe parts.... what do these do ?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-17 03:21:43 UTC
From: oddjob@oz.plymouth.edu
Message-ID: <1992Jun17.032143.20990@oz.plymouth.edu>
Source record: 43981

[It's a LONG story but.. ->I took apart my Mega STe to see what it had inside & why it SEEMS to have a 1.44meg floppy but the option to format the things doesn't show up...]

Can anyone tell me what the following chips/jumpers/etc are/do on a Mega STe ?

Chips Location on m/b* Description

C301907-001 $3A35 near power supply 20 pin DIP
C301907-001 $2EC4 near power supply 24 pin DIP
C301712-001 right of VME slot square 64pin
WD1772-PH right-hand side of m/b **
INMOS8927-B (2) lower left corner of m/b

Empty sockets Location on m/b* Description

UB1 near UB2 20 pin DIP
UB2 below 68000 64 pin ***
Spare 1 right side of m/b 20pin DIP
Spare 2 right side of m/b 24 pin DIP

Jumpers Location on m/b* Description

W3 next to UB2 2 pin jumper
W202 next to ROMS
W201,W202 between ROM's & SIMM's
J290,J291 near monitor port J290 is
connected to
power-on light
W401,W402
J402 far right on m/b 15 pin pairs
->1st 8 w/jumpers
Misc.....

The is a DIP switch in the lower right hand corner of the m/b. In my machine ALL of the switches are in the down position.

My disk drive is an EPSON SMD-380. Is that a 720K or a 1.44meg drive ? If it is a 720K drive why does it have the detect pin for 1.44 meg disks ?

* m/b = motherboard
** = This is the floppy controller chip, isn't it ? Is the AJAX chip pin compatible ? & This is why I can't format HD floppies... %-)

*** = I'm assuming that UB2 is where the 68881 (?) math co-processor
goes & jumper W3 tells he ST if it is there....

Anyanswers to my questions about these would be appreciated.....
Thanx,

-Andy-

2381. Emacs BS/DEL remap

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-17 08:36:30 UTC
From: mintha@geog.ubc.ca
Message-ID: <1992Jun17.083630.3488@unixg.ubc.ca>
Source record: 43984

There seems to be a demand for the code to remap the backspace
and delete keys, to there normal (at least in our part of the
computer world) functions in emacs. I use this on the suns
at school, and it seems to function fine on my ST as well. There
are simpler ways of doing this, but this way you don't lose any
functions. Just stick this in you emacs.rc (.emacs) file.

It maps the backspace key to send DEL (and hence the function
delete-backward-char) The delete key to send \C-\, and sets
that to the function delete-char. And finally it remaps
CTRL-\ to \C-h, which gives you the help functions. You can
add other keys. (for example, if you use flow control, then
you can't use CTRL-s for isearch-forward. Rebinding that funciton
to CTRL-u say, will not really work (at least on successive searches)
but if you were to use (aset keyboard-translate-table ?\C-u ?\C-s)
in the code below, CTRL-u would function exactly like CTRL-s.

If the above paragraph, makes no sense, don't worry, just stick
this code in, and Backspace, and delete will work properly. :)

```
(defun swap-ctl-h-and-del ()
"Swap the C-h and C-? keys at the lowest level. Beware, this will
swap related key-sequences as well: e.g., C-M-h and C-M-?"
(interactive)
;; First make a translate table that does the identity translation.
(setq keyboard-translate-table (make-string 128 0))
(let ((i 0))
(while (< i 128)
(aset keyboard-translate-table i i)
(setq i (1+ i))))
;; Now alter translations of some characters.
(aset keyboard-translate-table ?\C-? ?\C-\\)
(aset keyboard-translate-table ?\C-h ?\C-?)
(aset keyboard-translate-table ?\C-\\ ?\C-h)
(aset keyboard-translate-table ?\C-= ?\C-q))

(swap-ctl-h-and-del)
(define-key global-map "\C-\\" 'delete-char)
```

I noted in the documentation that an example of using fifos is in the
print utilities (i.e lpr and another related prog which I can't
remember the name of). I've been trying to find the sources
for these examples are as it would help to get me started but I have
so far failed. I was wondering
is anyone knows in which files at a.a/mint they are kept?

I did consider direct calls to mint but wasn't sure whether it was the right
thing to do, but know that I see that it is ok I'll give it a try.

Thanks for the help

Try looking in mntutl93.zoo in the "mint" directory at atari.archive.
It has both the binaries and sources for a number of sample programs
for MiNT.

2386. Backing Up Minix From Tos (again)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-17 16:30:43 UTC
From: malay@sae.com
Message-ID: <1992Jun17.163043.4496@sae.com>
Source record: 43990

My original query received several replies which stated that I should use "mint094b.zoo" and "mfs055.zoo" - well, I ftp'ed these files, unpacked and installed them. My Minix partitions are now visible from TOS except that the backup programs (BackupST and DiamondBack II) convert the Unix file names into TOS's 8.3 format. Question: Is it possible to back up a Minix partition from TOS without having the file names changed? Will GNU Tar work from TOS. I also need multi-volume support.

>There is a DIP switch in the lower right hand corner of the m/b. In my
>machine ALL of the switches are in the down position.
Someone suggested I set switch 7 on this DIP to the other position to
get the HD Format option to work. I did that but I still can't format
HD disks. I guess I'll have to spend the money for the OTHER pieces. I
just need to know if -->
>My disk drive is an EPSON SMD-380. Is that a 720K or a 1.44meg drive ?
so I won't have to buy a drive also.

>If it is a 720K drive why does it have the detect pin for 1.44 meg
>disks ?
More to the point, why DOESN'T the Mega STe not know the size of disk
in the machine. Setting the HD Format option causes errors..... when
trying to format 720K floppies.

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-17 17:30:04 UTC
From: bpat@cs.mcgill.ca
Message-ID: <1992Jun17.173004.2852@cs.mcgill.ca>
Source record: 43893

You do not need to have your routine redraw the sprite. Just call Line-A to get the mouse pointer active again. The thing is, the mouse is still there, but hidden (By a call to VDI's v_hide_c()). Of course, VDI cannot be accessed and so v_show_c() is out of the question (Although I haven't tried it myself, so maybe this function does not REALLY need appl_init() or v_openvwk(), but one thing that's sure is that Line-A does the trick !!!.

2390. GCC 2.1: shrinking executable size

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-17 17:40:48 UTC
From: torrance@ai.mit.edu
Message-ID: <TORRANCE.92Jun17134048@cookie-monster.ai.mit.edu>
Source record: 43891

In comp.sys.atari.st I asked:

>Can anyone explain how to make GCC 2.1 produce smaller executables on
>the Atari? How, for example, do I use the "integer only" libraries
>iio.olb, and will this decrease the size of the executable programs I
>create? All of my executables are about 30-32 K for even small
>programs with minimal integer only I/O, and I think this is too big.

I got this response immediately, which I found very helpful and I
thought others might as well:

(from Stephen Neuhaus-Hilgardring:)

Offhand, I can think of these solutions:

* Strip the executables, keeping only the __stksiz symbol (this is a
neglegible overhead).

* Don't use printf(), fopen(), use Cconws(), Fopen() instead. That's
stupid if you want portability, but great if you want small programs.
You don't need all the machinery of printf() in most cases so you
could write your own conversion routines.

* Use 16-bit integers.

* Use -O2 in the GNU compiler options.

To use iio.olb, just add -liio to the linker command line, e.g.,

gcc -o foo.ttp foo.o bar.o -liio

then, do the following

strip foo.ttp

or, if you want to keep __stksiz, use

strip -k foo.ttp

(I have tinkered with strip myself, so the switch may be named
differently from your implementation.)

Have fun.

Oh, BTW, my more thrivial programs never exceed 20K or so, and I use
32-bit ints and no -iio. I do strip, though (the executable, of
course, not myself :-).

> | Darn Good Reason(tm).

This is off of the top of my head, but I believe you only need to
remove the driver program off of one of your disks. I went from AHDI
to the Supra driver on my hard disk because I wanted 32 Meg partitions
with 1K clusters. All I had to do for the initial change over was to
remove the AHDI boot program from the hard drive and use the Supra
utilities to install SupBoot. I guess that you should try and boot
from a floppy instead of from the hard disk and then run the Supra
Utils to remove SupBoot from your external drive. You can do this by
powering up your drives after your computer and then manually run the
floppy boot program (you may also need to reinstall the drive icons,
but that's easy 8-).
No Guarantees, but then this isn't hard to do either.
Good luck,
Bob Pegram

2394. makefiles and Heat-n-Serve

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-17 19:44:31 UTC
From: vicb@clark.edu
Message-ID: <1992Jun17.194431.22045@clark.edu>
Source record: 43894

Could someone please e-mail me a couple of MAKE.INI and .MAK files that they use for Heat-n-Serve C? I can't seem to get this to work the way I think it should...the MAKE.INI file I got with it had a typo I think, and didn't include a '.o.prg' rule, but when I put one in there myself I get a "make: no target provided near line 71" message, and line 71 of the .INI file is the .c.prg etc. rule. Apparently I don't have a clear understanding of how it should be done, a few examples that work for other people should help out. Also, that typo? Well, it was like this: "LD = cc.ttp" Doesn't seem right. When I changed it to ld.ttp and added the .o.prg rule, that also produced the same 'no target' message. If I use the .INI file as is, with just the line "iconmake.prg: $(OBJ)" as the meat of the makefile, it compiles to object but doesn't link the things into the .prg file. Any examples involving multiple files and the corresponding .INI used will be greatly appreciated. Thanks-

Victor Bruhn

>C301907-001 $2EC4 near power supply 24 pin DIP

Not sure, but I think these are the ROMS (each are 256kx4, right?
or was it 128kx4?). Whatever they are, they are obviously related, but
WHY do they have different pin configurations?

>C301712-001 right of VME slot square 64pin

Got me. VME controller/buffer/PLA array maybe?

>WD1772-PH right-hand side of m/b **

Bingo. That is the floppy drive controller that the AJAX replaces
(and one of the DIP switches needs to be switched - don't know which tho.)

>INMOS8927-B (2) lower left corner of m/b

These are the serial port chips for ports 2-4 (I believe - I know
that the LAN port/3rd RS232C definately uses the INMOS chip, but I am not sure
if the 2nd RS232C port uses this too. Port one should use the normal UART.

Unfortunately, I don't know much about the sockets/jumpers, but
here are some guesses:

> Empty sockets Location on m/b* Description
>---
>UB1 near UB2 20 pin DIP

Probably some glue-logic for running the co-pro (see below). Like
maybe some inverters or NAND gates possibly.

>UB2 below 68000 64 pin ***

Most likely the 68881 co-pro slot. Especially if it shares a lot of
the lines running from the 68k.

>Spare 1 right side of m/b 20pin DIP
>Spare 2 right side of m/b 24 pin DIP

Hmm. Sounds an aweful lot like the chips that above I (guessed)
labled as ROM chips. If they are ROM sockets, perhaps this is for updated
ROMs (can you say MTOS? I knew you could ... :). Or perhaps they have
nothing to do with the obove sockets...does it look like they share a lot of
the same signals (that is if they are close enough for you to tell)?

>
> Jumpers Location on m/b* Description
>---
>W3 next to UB2 2 pin jumper

Probably co-pro enable.

>W202 next to ROMS

Probably ROM type :ie, old ROMs had a different starting address
than the new ROMs (see the TEC board).

>W201,W202 between ROM's & SIMM's

Hmm. RAM size? RAM speed? Got me...

???????

>Misc......
>-----------
>The is a DIP switch in the lower right hand corner of the m/b. In my
>machine ALL of the switches are in the down position.
>

These are the main control switches. One swtich enables 1.44 drives,
two (three?) enable SCSI offset, one enables multi-HDs on the SCSI bus (I
think that this is disabled on the MSTe ... I reserve the right to be wrong
tho.) Someone was posting earlier about the last two - might ask them which is
which.

>My disk drive is an EPSON SMD-380. Is that a 720K or a 1.44meg drive ?
>If it is a 720K drive why does it have the detect pin for 1.44 meg
>disks ?

This is a 1.44. They don't build 720K drives with two (hole)
detectors. I know, I'm asking to get tromped about this, but it doesn't make
sense to waste money putting it in there if it isn't gonna get used.

>* m/b = motherboard

>chip that is needed 'AJAX' I think.
Atari Benelux has announced their own upgrade kit for this containing
TOS 2.06/3.06, AJAX, and a disk drive that has the same front panel as
the original ones. They will also sell the parts of the kit separately.
Especially the disk drive is of interest, since other ones require modification
of the housing.

> Anybody know of a Source in Europe ??
I've seen a British firm selling ST parts on a Dutch fair, I think they
are called "Best Electronics". If you cannot locate them, you might try
the more-or-less official Dutch parts dealer:
ATIN electronics
P.O. Box 16069
2301 GB Leiden
phone 071-153555 (this the number to dial from The Netherlands)
They accept VISA, AX and EUROCARD. I don't know if they are prepared
to ship abroad.

> Apart from replacing the drive, the floppy controller chip and
>upgrading TOS to 3.06 what else must I do.
At least for a Mega STe, Flip dipswitch 7 to enable the HD selection button
in the formatting dialog form.

as spake by torrance@ai.mit.edu (Mark Torrance) :
>* Don't use printf(), fopen(), use Cconws(), Fopen() instead.

May not help, unless the library has improved a lot recently. For
instance, in the MiNTlibs PL <=19, the startup code called malloc(),
which used the assert() macro, which used the library function
__eprintf(), which called fprintf(). The simple program
`main() {return 0;}' dragged in nearly 12K of library code. Since the
MiNT libraries were derived from the GCC libraries, the situation is
likely as bad there.

<List of unidentified parts deleted>

To test if you have a HD drive, simply set dipswitch 7 to ON.
This should enable a new button in the dialog form you get when
you format a floppy. This new button allows you to select formatting
of HD floppies.

As far as I know, no other dipswitch has any function at the moment...

2399. Screen redraws

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-17 21:30:53 UTC
From: i921652@redgum.ucnv.edu.au
Message-ID: <1785@sheoak.bcae.oz.au>
Source record: 43906

I am writing a simple program using Personal Pascal. All I need to do is swap as quickly as possible between two degas screens. The only problem is that it flickers quite badly, even though the swap rate is satisfactory. I assume that this is because the screen is not being redrawn in sync with the display. How can I wait until the screen is about to be redrawn before I call my display procedure?

Thanks in advance for any help offered.

Jared Quinert

> >work exactly right. Does anyone have any advice/help/tips? Please?

HighSpeed Pascal supports the Execute call, which is fully documented in
both the manual and the on-line help system. Control will return to
your program when the child process terminates.

Shel_write does nothing until your program terminates, then the AES shell
will launch the specified application. When it terminates, control will
return to the desktop, not your application, which isn't what you want.

How many HighSpeed Pascal users are out there? I thought I was the
only one.

There are two ways to get Mac MIDI running under Spectre: hardware or
software. The easy way is to provide exactly the hardware that the MIDI
software is expecting for serial control and timing functions. That is,
a MegaTalk board.

Software would be the hard way, but should be possible. Most Mac MIDI
software these days will work with the Apple MIDI Manager, which relies
on a MIDI Driver to provide an interface layer between the Manager and
the hardware. If you disassembled the MIDI Driver, you could probably
rewrite those sections that accessed Mac-specific hardware to access
Atari-available serial chips and timing clocks. The result could not
be distributed, since it would rely on Apple copyrighted code, although
it might be possible to generate a difference file that could be applied
to an Apple MIDI Driver to transform it into an Atari MIDI driver.

Atari France sell it, and there is somewhere in Paris a place to buy it.
However, you don't need AJAX to handle 1.44 Mb disks. I have such a drive
in my TT, and I have changed nothing at all, execpt the 7th switch.

Even TOS 3.05 handles High Density.

So do nothing, and give up searching for the AJAX !

Vince.

2407. Serpatch and TT TOS 3.0.6?

From: vspicer@ccu.umanitoba.ca
Message-ID: <1992Jun18.143807.9268@ccu.umanitoba.ca>
Source record: 43908

does anyone out there have problems with TOS 3.0.6 on a recent-model TT030 talking to serial/modem ports? our new TT's, with TOS 3.0.6 (??- a version checking program says it's 3.6), simply won't work on modem1, or modem2. we have tried Stalker, Uniterm and Atari's VT52 emulator all with no luck. it's not the line settings or the link, we've got it working fine on an earlier model TT with an earlier version of TOS.

some suggested installing serpatch in the auto folder. it comes up saying serpatch isn't needed for versions of TOS above 3.0.5 :)

thanks in advance
vic spicer

2408. AtariCSI/SCSI bus access on ST's TT's

Newsgroup: comp.sys.atari.st.tech

Source record: 43913

Hi netters,

I am looking for descriptions on how to send and receive commands/data on the Atari SCSI like bus. If there is any public domain C bindings, that would be very usefull too. Description of calls to the standard HD driver would probably do the same job.

Is there any program under GNU which uses direct calls to the HD drivers?

Thanks in advance

Mustafa Soysal

Jared, you need to use vsync() to wait for the next vertical blank interrupt
before doing the swap. vsync() is at XBIOS(37).

2414. How to check what the baud rate is?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-19 01:30:34 UTC
From: hunt@cthulhu
Message-ID: <1992Jun19.013034.18014@spdcc.com>
Source record: 43915

Hello, I'm writing a program that does funky stuff with the modem.
I am hoping that there is a better way to determine the baud rate
that the user connects at rather than printing a "press return" string at
each baud and waiting for the response...
All the source I have found dealing with the modem does it that way, which
seems a really lame way to do it.. I mean even the C64 BBS's can determine
what BPS you are at without doing that!
Anyone have any ideas?
Thanks,
Tad Hunt

I thought this kind of thing was handled by the modems at either end.
That is, if you call a 9600 BPS modem, it will detect what speed the calling
modem is using and establish a connection at that speed, even if it doesn't
happen to be 9600 which might be the default. Perhaps you can watch the
modem result codes and it should tell you what speed the connection is at
so that you can correctly set up the serial port.

The Compute book, Volume 3: TOS, says that setscreen should occuring to Atari
wait for the sync but it doesn't thus requiring the use of vsync()

>have tried Stalker, Uniterm and Atari's VT52 emulator all with no luck. it's
>not the line settings or the link, we've got it working fine on an earlier
>model TT with an earlier version of TOS.

My guess would be that there is something wrong either on your
motherboard or (more likely) with the connectors or wiring in the TT.
If none of those programs have any luck then I think you can rule out
a software problem, unless somehow your copy of TOS 3.06 is brain
dead. I'm running TOS 3.06 on an early-issue TT and am able to use
all the ports under STalker, so the problem isn't TOS. I know a
couple of people around here that have new TT's (3.06, 1.44M floppy)
and they haven't reported similar problems, so my first guess would be
your hardware.

Do you have any luck with Serial 1? It's hooked up to the 2nd MFP
(Modem 1 is the 1st MFP, Modem 2 and Serial 2 are from the SCC chip).

Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech,misc.comp.forsale

In an attempt to get some cold hard cash, I need to sell my TT.
The package includes:

TT030 Computer w/ 4MB ST RAM
50MB internal hard drive
PTC1426 color monitor
Cordless mouse

All for the low asking price of $2000.
If you are interested, make me an offer.

Besides the above, you get all the other TT features like VME, LAN,
multiple serial ports, higher rez, etc.

>
>Dave
The normal ST 'syncs' no matter what you do, 'coz the internal video
counter is refreshed from the screen address register, whenever a new
screen begins. So on a normal ST you can't mess up the display writing
to the screen address register.

The amusing thing is that when you call Setscreen, you don't know when
the flick's gonna happen. Although Setscreen DOES wait for one vertical blank,
to update the VT52 (got this from the TOS listing), it sets the video
base beforehand (the OS or the chip videobase I can't recall at the moment).

For game writing Setscreen is a bad idea, 'coz you might lose enormous
amounts of CPU cycles just waiting for an VBL. (if you care about your
code, don't use either Vsync(), not Setscreen() if you got something else
to do besides just showing pictures)

Using a deferred VBL routine, to set V_BAS_ADR (*), isn't too good either,
(I don't swear on this one), since you end up waiting two VBLs for the
flick.

The trick for reliable screen flicks is to know WHEN to set which
address.

If there actually is some interest I might be willing to part with a
little code, that helps doing animation. (But I need to dig it up at home,
so I can't include it now)

Nat!
[Information above w/o guarantees]

(*) the OS video base address at $4... something

Wait a second. You're not telling the whole story. :^)

Simply switching dipswitch 7 to on only makes the High Density button appear in the format dialog box on the desktop. If you aren't HD-capable yet, it will still be greyed out.

I have everything installed in my (old) Mega STE: 1.44meg drive, AJAX, TOS 2.06, dipswitch 7 set to on, and yet I still can't format a 1.44meg disk. I'm waiting for my dealer to receive some parts from Atari; waiting forever by the way. :^(I'm waiting for a new PAL and an address line trace is required.

To eliminate flicker you need to double-buffer; if you write to a
screen that is currently visible, you most definitely *will* get
flicker, regardless of the way Setscreen behaves.

You need to explicitly vsync after calling Setscreen because otherwise
you won't know when to stop drawing on the current hidden page and
start drawing on the new hidden page. Setscreen returns immediately;
it just doesn't *take effect* until the next vertical blank. If you
ever draw to a page you *think* is hidden but actually is not (which
you will if you don't explicitly vsync) then you're drawing to the
physical screen, and you'll get flicker.

>For game writing Setscreen is a bad idea, 'coz you might lose enormous
>amounts of CPU cycles just waiting for an VBL. (if you care about your
>code, don't use either Vsync(), not Setscreen() if you got something else
>to do besides just showing pictures)

I couldn't disagree more with this. You *should* use Setscreen and
Vsync for all animation on the ST. Using the Xbios ensures that your
code will work even if the operating system or hardware registers
change, and doesn't cost you anything extra. Any way you slice it, you
must wait for the vertical blank after changing the physical screen
pointer (i.e., after page flipping). The proper way to deal with cycle
lossage is to sync the game to every nth vblank and then drive it to
the wall by adding sprites, sounds, or whatever until the time you're
"wasting" is small.

An additional benefit of vsyncing is that, if done properly, it ensures
that your game will run at the same speed on every machine. This
prevents the game from getting unplayably fast on faster CPU's, a
notorious and very amateurish effect.

Are you sure about that ? I set DIP switch 7 to on & the HD Format
button is visible but NOT greyed out. The difference is that it chugs
away at floppies for a little while & says that there is something
wrong with the floppy inserted in it. I AM able to click on that
option.

I wonder if anyone else who (possibly) bought their Mega STe from
Joppa has the 1.44meg drive but no AJAX chip.

Where can I get the AJAX chip (cheap) ???

2427. bitblit problem

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-20 06:12:19 UTC
From: vicb@clark.edu
Message-ID: <1992Jun20.061219.9004@clark.edu>
Source record: 43927

I am having a small problem getting the vro_cpyfm() call to work correctly.
Any programming aces out there that can help? Bit Blitting is new to me...

The problem is not in getting the form written to the screen-it's
getting the colors to behave. The only color that comes up right for
sure is the background- everything else is different then it should be.
I am using a mode setting of 3 (source data, no bit operations). Any
pixels not set to the background color come up a different color than
the color number corresponding to the bitplanes. An icon defined as
(lo-res, 1 word width)
(hex) 8000 0000 0000 0000 should return a single pixel set to
color register #1, however I get color 2...
(hex) 8000 8000 8000 8000 should have a pixel set to color #15,
but I get color 1...
Experimentation has revealed no pattern, and the basic icon always has
the proper shape/dimensions/etc, so I know I'm doing the setup and calls
correctly, but I must be misunderstanding the bitplane relationships
regarding color selection. I am using Heat-m-Serve C on a 2 meg STe.
Thanks in advance,
Victor Bruhn

From: rdo@kynes.bison.mb.ca
Message-ID: <H.PchsMNYfA7c@kynes.bison.mb.ca>
Source record: 43928

I have a few questions on symbolic links:

1) Can the SLN command in mint.cnf create links to files as well
as directories?

2) Does the GNU utility LN work with MiNT? I've read the man
page but can't get it to work.

3) If LN won't work, is there a way to use SLN after MiNT is invoked?

4) Or, do I have to wait for MultiTOS and then the universe will
start unfolding as it should?

This depends on which version of ln you're using. The one compiled with the MiNT libraries does; the one compiled with UNIXMODE does not. Note that even the MiNT one (found in mint/futil* on atari.archive) will work only on file systems that support symbolic links, i.e. in the root of drive U: or on any minix-formatted disks. You can't make a symbolic link on a normal TOS disk.

> 3) If LN won't work, is there a way to use SLN after MiNT is invoked?

See the manual page for Fsymlink() in the MiNT docs.

Well that's basic game design. But the original poster said that he wanted
to switch between two DEGAS screens, which in my eyes are static.

>You need to explicitly vsync after calling Setscreen because otherwise
>you won't know when to stop drawing on the current hidden page and

^^^^^^^^^^^^^^^^^^^^^^^^^^^^
Yup you're right obout this, I misread something in the OS listing.

>>For game writing Setscreen is a bad idea, 'coz you might lose enormous
>>amounts of CPU cycles just waiting for an VBL. (if you care about your

Working with just Vsync() and Setscreen(), you still have the problem of
not knowing when your done, or whether you have gone overboard. At the time
of the Setscreen call, how do you know where you are in terms of screen
redraws ? I was wrong about Setscreen(), but I still think that way about
Vsync().

Lemme show how I do it. It works like this: There's a deferred VBI running
that flips the screen at the rate of the VBL divided by SLICE.
(So far since this is from a mono game, I just flip at 17Hz) The redraws go
like this

0 1 2 3 0 1 2 3 0 ..
[AB][AB][*AB][AB][BA][BA][*BA][BA][AB][...]

where every [] is a VBI, the first letter is the screen currently drawn
on and the second letter is the screen currently shown. The * indicates
when the VBI sets SCREENPT. Since SCREENPT gets loaded into DBASE at the
next VBI, and from then the screen will flick only at the next VBI, you have

```
to do it two VBI's in advance.

/* an excerpt: Hope this runs OK, since I edited it quite a bit */

#define byte unsigned char
#define word unsigned int
#define lword unsigned long

#define VBLSEM (*(word *) 0x452)
#define NVBLS (*(word *) 0x454)
#define VBLQUEUE (*(void (**)()) 0x456)
#define SCREENPT (*(word **) 0x45E)
#define FLOCK (*(word *) 0x43E)
#define FRCLOCK (*(lword *) 0x466)

#define SLICE 0x4L

extern word *drawscr, *showscr, *scrA, *scrB;

int slicecounter,
vbi_mode = -1,
reached_it,
exhaustion;

void animate()
{
word *tmp;

vbi_mode = -1;
restart:
FLOCK = 1;
showscr = scrA;
drawscr = scrB;
Setscreen( (void *) -1L, drawscr, -1); /* This ain't the interesting one */
slicecounter= -1;
vbi_mode = 1; /* reset VBL */
while( slicecounter < 0); /* wait for first hit */

do
{
tmp = showscr; /* now do the flip */
showscr = drawscr;
drawscr = tmp;

... do whatever you want in here on `drawscr' ...
... the vbi will do the flipping ...
... Don't forget to set vbi_mode to -1 when leaving this ...

reached_it = 1; /* must be there before the VBI */
while( reached_it); /* burn up leftover cycles */
}
while( ! exhaustion);
```

```
anim_stop();
nferror("Timeslice exhaustion");
}

/* ---------------------------------------------------------
This is the vbi_routine that synchronizes the drawing.
slicecounter counts the VBIs. When the SLICE value has been
reached, then at the NEXT vbi the screen will, be switched
physically!
If the to be synchronized routine, can't set reached_it,
the vbi assumes, that the CPU was too slow.
This particular routine works only with SLICE values > 1

Control this VBI with vbi_mode:

0 : normal operation
-1 : sleep
1 : reset VBI
--------------------------------------------------------- */
void vbi_routine()
{
if( vbi_mode >= 0)
{
if( vbi_mode)
{
exhaustion = vbi_mode = 0;
slicecounter = 0;
}
else
if( slicecounter++ == SLICE - 2)
SCREENPT = drawscr;
else
if( slicecounter == SLICE)
{
if( ! reached_it)
exhaustion++;

reached_it = slicecounter = 0;
}
}
else
SCREENPT = 0;
}

vbi_linkin( f)
void (*f)();
{
int i, val = 1;
void (**p)() = VBLQUEUE;

VBLSEM = 0;
for( i = 0; i < NVBLS; i++, p++)
if( ! *p)
```

```
{
*p = f;
val = 0;
break;
}
VBLSEM = 1;
return( val);
}

void vbi_linkout( f)
void (*f)();
{
int i;
void (**p)() = VBLQUEUE;

VBLSEM = 0;
for( i = 0; i < NVBLS; i++, p++)
if( *p == f)
*p = 0;
VBLSEM = 1;
}

anim_init()
{
#if ! NOVBL
if( vbi_linkin( vbi_routine))
nferror("We ain't good enough to linkin a VBL properly");
#endif
}

anim_stop()
{
vbi_mode = -1;
SCREENPT = 0;
#ifdef ALLSPEED
FLOCK = 0;
#endif
}

anim_exit()
{
anim_stop();
#if ! NOVBL
vbi_linkout( vbi_routine);
#endif
Setscreen( showscr, showscr, -1); /* no confusion */
}
```

If you wanted you could call Setscreen in the VBL instead of setting SCREENPT, but then you'd need to flip the screens one stage later.

The positive thing is that as soon as the switch has been done, drawing resumes on the new drawscreen. The code never has to explicitly sync to the vertical blank using Vsync(). Since using Vsync() the OS is burning the cycles, you can only regain them by interrupts.

I'd be interested to know, how you do it, apparently just with Vsync() and Setscreen(). Honestly!

==========
I have been sucessful in uning both SUPBOOT and AHDI together, but there are some tricks: First off, with multiple volumes, you must have sequential SCSI ID's. In my case, SCSI-0 was a Supra formatted drive with 16MB partitions C,D,E,F,I,J,K,L,M. Partitions G,H were "dummy partitions only 1MB in size. What would happen is that upon bootup via FLOPPY, SUPBOOT will load partitions C-M off of SCSI-0. Then AHDI will run, and SCSI-1 (a Syquest 44MB "BGM" partition) becomes partition G and SCSI-2 (a ST-277N 60MB "BGM" partition) becomes partition H.

My interpretation of this is that AHDI sees only 4 paritions per physical drive, and therefore "grabs" the fith partition position (G), causing the G parition on SCSI-0 to be phantomed out. OF course, H gets overlayed also once SCSI-2 is mounted.

As you can guess, I purposely formatted G and H on SCSI-0 at minimum size, since they are overlayed by SCSI-1 and SCSI-2. Partitions C-F and I-M remain uneffected, though I assume that if I had mounted a SCSI-3 I would phantom out partition "I" on SCSI-0...

Oh yeah, if you try this, I recommend FLOPPY boot. It saves a lot of grief. Also, AHDI must be the last program to run in the AUTO folder. (and AHDI needs SCSI id's in sequence- You can't have a 2 drive set-up with SCSI id's 0 and 2; It must be 0 and 1)

Hope that helps...

2435. Minix file system under MiNT

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-20 14:19:13 UTC
From: sundsted@cis.uab.edu
Message-ID: <1992Jun20.141913.10060@cis.uab.edu>
Source record: 43931

I am interested in creating a Minix file system on one of my HD partitions
under MiNT, however, I am unsure of what must be done. I have the minix.xfs
zoo file and have read all of the documentation, however, it doesn't
explicitely say what to do. I assumed that the minix.xfs file
must be executed and added the following line to my mint.cnf file

exec /sys/minix.xfs (where minis.xfs is in dir sys on u:/)

when this executes I get a bus error. So, is this all I need to do
or am I missing something?!?

2436. Re: GCC 2.1: shrinking executable size

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-20 15:53:32 UTC
From: ntomczak@vega.math.ualberta.ca
Message-ID: <ntomczak.709055612@vega>
Source record: 43933

There are ways to shrink executables. It depends what you are doing, how much effort you are willing to spent, and what do you expect from results. This program:

```
#include <minimal.h>
#include <osbind.h>

main()
{
Cconws("Hello world!\r\n");
}
```

with '-O2 -s -mshort' options compiles to 1203 bytes of executable. BTW - gnulib is (or better, production code usually is) compiled with -DNDEBUG option so assert() macro vanishes in preprocessor. Check your makes!

2437. GCC-compiled programs ignore keystrokes under plainTOS

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-20 18:48:34 UTC
From: stenny@troja.stgt.sub.org
Message-ID: <0810.06.92@troja.stgt.sub.org>
Source record: 43747

Hi!

I'm asking for advice, with a strange effect in my software.
Some of my gcc-compiled programs ignore any keystroke, when launched under plainTOS, but they work fine, if fired up under MiNT.

All of these programs are linked with MiNTlib PL20 and compiled with GCC 2.0 PL2.

The first of these programs is less 1.77. I took the original *IX source from our local ftp server's unix/gnu directory and compiled it without any ST-specific changes. All sources compiled well and the program works perfectly under MiNT.
I tried it under TOS and it seemed to work. But then I recognized, that my favo(u?)rite shell had the ARGV-scheme implemented with errors. So I patched the shell. No it writes the string `ARGV=0123456789' to the environment, as the ARGV trigger. As soon, as I start less from this patched shell, it comes up and displays the first page of text, but refuses to do anything further. The program seems to ignore every and any keystroke. The only way to quit less is to press `CTL-ALT-DEL' :-(
If I start the ame program from the unpatched version of the Shell, which writes only `ARGV' to the environment (the `=' is omitted!), less runs!

The second program is GNUemacs 18.57. I recompiled the program using MiNTlibs PL20. It runs really fine under MiNT and tcsh, but refuses to read the keyboard, if launched from any shell under plainTOS. I tried to get emacs to work from my patched and unpatched Shell and from gulam - the result remains the same: I have to reset my computer, because emacs doesn't react to any keystroke.

Does anyone have an idea, that could me help to solve this problem?

Yes, I also know about this card. Its specifications are really nice at that price. But it is rumoured among German Atari insiders and distributors that Omega seems to be a company which often advertises for products they cannot ship. Nearly everyone I asked about Omega told me the same. I would be very cautious before ordering one.

Message-ID: <lahtinen.709122966@gideon>
Source record: 43742

I downloaded gcc 2.1 from a.a and with the helpfull notes from
this group I managed to install it. Now I can compile programs,
but I did not manage to find a working make-program.

From a.a I found two versions of gnumake. Version 3.62 was not
working at all. When I tried to run it from Mupfel it complained
"not enough memory" and indeed after it there was only 15 KB free
(I am using MultiGEM). Version 3.60 was working better, exept
I think it is so clever that it tries to compile .cc programs with
g++.

Also I noticed that there is some problems with setenv and Mupfel.
It seems to me that the program I start does not see these parameters.
I tried to use also bash under Mint 0.94, but I was not much luckier.

So I would be happy if someone could give me some help!

>root of drive U: or on any minix-formatted disks. You can't make a
>symbolic link on a normal TOS disk.

what about the posibility, to reinstall a directory-link, if one removed
the wrong link from u:/?

It happened to me, that I did a 'rm /bin', instead of a 'rm /tbin'. But
all efforts, to reinstall the link failed.
I called `ln -F c:/bin /bin', ln `-F /dev/C/bin /bin' and `ln -F /c/bin
/bin'. But every time I got the message: `cannot link ... rename across
drives'

It is no problem, to install a symbolic link from any file to a file in
u:\, but it seems to be impossible, to install directory links, with ln.

>redraws ? I was wrong about Setscreen(), but I still think that way about
>Vsync().

The program itself doesn't know how close it's getting to the end of
the frame, but you (the programmer) tune the game to the number of
vsyncs per game that works at the minimum CPU speed you intend to
support. (In our case, probably 8Mhz.)

Neil Forsyth came up with a good way to see how close your game is
getting to the end of the frame; you just change the background color
to 0x777 right before you call Vsync. (This assumes your normal
background color is dark.) Using this simple technique you can tell at
approximately what scanline you're calling Vsync.

> reached_it = 1; /* must be there before the VBI */
> while(reached_it); /* burn up leftover cycles */

It seems like this part of your code is doing the same thing Vsync is.

>The positive thing is that as soon as the switch has been done, drawing
>resumes on the new drawscreen.

But *after* the while loop above, right? It seems equivalent to me,
but I may be missing your point.

>I'd be interested to know, how you do it, apparently just with Vsync()
>and Setscreen(). Honestly!

OK, here's the real vsync code from Game Workbench:

```
*------------------------------------------------------------------------*
/*
* Wait 'til at least n vblanks have passed.
*
* Modification History
*
* 6/7/90 dmb Created.
* Hacked around some compiler brain-damage.
* 6/10/90 dmb Rewrote it to call Bios Vsync for guaranteed
* compatibility with all TOSes.
*/
```

```
#include <system.h>
#include <osbind.h>

#include "vsync.h"

#define FRCLOCK *((unsigned long *) 0x466L)

unsigned long _vc;
unsigned long _vclast = 0;

/*
* This routine must be executed in supervisor mode.
* It returns the number of vblanks that have occurred since bootup
* through the global variable _vc.
*/
void
_vcount()
{
_vc = FRCLOCK;
}

void
vsync(n)
unsigned int n;
{
do {
/*
* Wait for next vblank
*/
Vsync();

/*
* Get current frame number in _vc
*/
Supexec(_vcount);

} while (_vc - _vclast < n);

_vclast = _vc;
}
*-------------------------------------------------------------------------*
```

Note that the vsync routine waits as long as necessary to ensure that _at least_ n vertical blanks have passed since the last call. If will always sync at least once, but may sync as many as n times, depenending on how much time there is left to burn that game turn. HacMan II calls this routine with a 4 for the first 100 boards, which means that at times when nothing much is happening (e.g., there's only one sprite on the screen and no sample is playing) this routine will wait for 4 vsyncs. When the game is "busier" this routine may return as soon as the next (single) vertical blank has passed. This self-adjusting algorithm prevents two common problems with game animation:

1. Game becomes faster (even unplayable) on faster machines
2. Game speeds up when few enemies are on the screen, or
slows down when things get "busier."

A properly tuned game will do neither of these.

And here's an excerpt from the main animation loop. I've deleted most
of the actual code but left in the comment that describes the general
algorithm.

```
*-------------------------------------------------------------------------*
gw_animate()
{
/*
* o Refresh new screen
* o Update page counter and screen pointer to point to new screen
* o Draw sprites on new screen, saving backgrounds along the way
* o Make new screen visible
* o Synchronize with the vertical blank to prevent flicker
* o Erase sprites from previously visible screen
* o Update sprites (do animation)
*/

[...]

/*
* Finally, we make the new screen visible.
*/
Setscreen(newpage, newpage, -1);
vsync(_kvsyncs);

[...]
}
*-------------------------------------------------------------------------*
```

Note that the vsync call is a call to the routine given above. This
works on all versions of TOS and never produces flicker. Getting
the Setscreen and vsync calls out of order will cause flicker.

I found that it still does need it with TOS 1.04. Although the out-of-
folder-memory errors are much less destructive they still occur and can
lead to problems. When I've had them it has been like a creeping paralysis
on my hard-disk, with more and more programs behaving oddly until all you
can do is zero the partition and start again.

Oops, I jumped the gun. As Phil Hartman on SNL says when impersonating Ed McMahon, "You are correct, sir. Yes." :^)

I think the reason I thought that it was greyed out was that Double Density is still selected initially and formatting at High Density causes the problems you described.

TH> I am hoping that there is a better way to determine the baud rate
TH> that the user connects at rather than printing a "press return" string at
TH> each baud and waiting for the response...
TH> All the source I have found dealing with the modem does it that way, which

All you really need to do is read the connect string from the modem (at the highest baud rate supported from the modem). There really isn't a way to just ask to ST what the baud rate is, because the modem is at liberty to change it.

2449. How to prevent double window scroll events: *a* solution

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-21 22:12:10 UTC
From: reeuwijk@dutentb.et.tudelft.nl
Message-ID: <1992Jun21.221210.27245@donau.et.tudelft.nl>
Source record: 43749

After the question I posted some time ago about spurious double window events, I would like to thank all people that have responded. Unfortunately, none of these responses contained the definite solution.

A few persons mentioned a program to fix this bug, called WINDFIX or variations thereof. I would like to know how this program works, but I don't want to use it, I would like to solve this in my own program. I have downloaded it, but I could not find anything in the documentation, and I 'd rather not dig around in the program itself.

Some other people suggested that I could copy the scroll handling code of the program XXED, since the window handling of this program would be correct. However, when I tried the program on my computer (Mega STe with TOS 2.06), the program had the same problem.

Finally, some people suggested that the extra events could be recognized by the fact that the mouse button was up, or by the fact that they occur together with other events. Unfortunately, neither of these things is true.

I have now found two solutions for the problem, although neither is perfect. The first solution is to wait for a double click of a mouse button in evnt_multi(). The second solution is ignoring scroll messages that immediately follow a previous scroll message. To do this I have used the following code in the message handler:

```
----
static void decode_message( int *buf )
{
static bool bogus_scroll = FALSE;

if( buf[0] == WM_ARROWED ){
if( bogus_scroll ){
return;
}
else {
bogus_scroll = TRUE;
}
}
else {
bogus_scroll = FALSE;
}
<actual handling code here>
}
----
```

To be absolutely sure that each scroll message is followed by an
other message, my handler for the scroll events forced a redraw
of a small area of the screen. I now use the other solution, however.

Source record: 43750

Well perhaps I was too hasty in saying that my system that has Tos 2.05
and a 1.44 meg drive installed is fine. I recently bought 2 boxes of HD
disks.. one JVC MF-2HD unformatted, and one Memorex Foamtted for PS/2's 2S/HD
disks. Now on to the oddity... is there anything different about those
formatted ones?
I can format the JVC's to 1.44 on and IBM or just fine here on the MegaSTe.
The memorex however, will not work after the first 700K or thereabouts...
information on the MSTe says the disks holds 1.44 megs.. but when trying to
copy to them NONE of the preformatted Memorex's will accept files once about
700K of the disk is filled. I then tried to reformat on the MSTe, but once
again about 1/2 to 2/3 of the way through the format I always get an error.
This is the same place on each of the memorex disks.
So.... does anyone have any idea on what could be the difference on the
preformatted disks that would cause something like this?

For the life of me I have looked in my MSTe and cannot find the ajax
chip, where exactly is it located and what is its part number of it
does not say ajax on it?
Did the fellow who started this thread have any luck so far? I would
be happy to trade notes with ya, since I too have a MSTe with 2.05 and a
144 drive installed. However I can format 1.44 but ONLY from the desktop
NONE of the external floppy formatters will work (at 8mhz or 16mhz) format
correctly at 1.44. Is THIS a 2.05 bug?
On my MSTe the only dip switch up is 7.

>yet, it will still be greyed out.

Are you sure? On my Mega STe (TOS 2.05, one of the 'early' ones), if I switch the DIP switch 7, I _can_ click on the HD-format box, but the disk can't be formatted! Perhaps because I used DD disks when I tried that, but I couldn't read HD disks either (without the switch, but that shouldn't make any difference, should it?). I don't think my Mega STe _is_ HD-capable!

I'm still quite confused about the different ways to upgrade to HD drives with TOS 2.05 or 2.06, and whether a new controller is necessary or not!

Perhaps someone would care to post some information on this subject, so that we (Mega STe users) finally know what we need for an upgrade. I know, there's the AJAX+TOS 2.06 update from Atari, but maybe all I need is a controller (WD 1772-2?) and a HD drive...

2455. background jobs in MINT.CNF?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-22 10:03:30 UTC
From: stenny@troja.stgt.sub.org
Message-ID: <0829.06.92@troja.stgt.sub.org>
Source record: 43767

Howdy!

you see the above question!
The reason for it is, that I tried to start lpd, the line printer daemon,
from mint.cnf as a background job, using bg.ttp
I included the following line in my mint.cnf file:
exec c:\mint\bg.ttp c:\mint\lpd.ttp
After mint was started, I saw a short message flashing to the screen,
telling me, that a bus error occured. I removed the `exec ... lpd' line
from mint.cnf and could start MiNT without an error. After reenabling the
exec, the error occured as before. Nevertheless, MiNT started normally,
but `ps' showed no line printer daemon. The only active processes found,
were 'MiNT', 'tcsh' and 'ps'.

Is it possible, to start background jobs with `bg.ttp' from mint.cnf, or
has this to be done later, after a shell is started?

stefan

Also DES contains `weak keys'. By duplicating two characters twice, you're probably very likely to get one of these ...

Try using XKEY.TTP (from the MiNT utilities) to map up, down, etc. to ^P, ^N
and so on.

Jens.

(I just compiled this - the port is by Erling Henanger).
(Also the binary is probably broken - it won't display documentation).

/ hpbbrd:comp.sys.atari.st.tech / sundsted@cis.uab.edu (Todd Sundsted) / 8:19 am Jun 20, 1992 /

Just put MINIX.XFS into the root directory of your boot drive (right next to MINT.CNF, that is). MiNT will find it.

Of course, you'll also have to set up a Minix partition with MINIT.TTP.

Good luck,

Jens.

BTW: Does anybody have a free fsck for Minix partitions ?

|> exec /sys/minix.xfs (where minis.xfs is in dir sys on u:/)
|>
|> when this executes I get a bus error. So, is this all I need to do
|> or am I missing something?!?

Yes! I've played a bit with it this weekend. I didn't want to scratch a
hd-partition, so I just took the floppy drive. All you've got to do, is
to put minix.xfs in the same folder as mint when booting, Note: when you're
booting mint from the auto folder, the root dir of your boot drive will be
appropriate, cause the actual folder is / and the programs are run by looking
for /auto/*.prg!
You must then use the minit.ttp to "minix-format" this drive (doesn't matter
if it's a floppy drive or a hd-part.) As mentioned, this will completely erase
the disk, all TOS data will be erased, and furthermore, TOS will never be able
to deal with this disk any longer, reacting in such a way, that it may kill
your minix data. So use the "protect with zero disk" option from minit.
You must do the above mentioned only the first time you'd like to use your
minix part.. Also, and all the other times, you've got to use mfsconf to
determine whether you'd like all filenames to be translated into upper case
letter and stuff like this. I've not checked this one so exactly, but I can
tell that the problem comes from the diferent way, minix handles its filenames,
exspecially that they can have both upper and lower case letters.

Hope this helps, TeSche

Actually not, except that i can see the same troubles with my MSTE and a
TEAC FD235HF floppy drive. It seems that it's impossible to access the upper
tracks (>40) correctly. I wrote a small program which just checks if it can
read random sectors correctly and display this on the screen. Coming back
after a break of two hours, the result was the above mentioned. This can't
be a question of the disks, so what else? Err, don't tell me about the MSTE
not being able to read them directly, cause I'm using one of these so called
hd-modules.

This is getting more odd by the hour...

1. We have people with older MSTe 2.05 wondering what options are
available to get 1.44 capability and/or 2.06.
2. We have a number of machines which were shipped with 2.05, AND
a 1.44 meg drive (like mine), however I still am trying to locate either
a 1772 or ajax chip in it.
3. We have at least one person who has a 2.05 MSTe machine with 1.44
drive yet he has a 1772, and his dipswitch 7 was not factory set.
4. Presumably all the new machines will have 2.06 and ajax/1.44?

BTW in my MSTe 2.05 with 1.44 like I said , haven't confirmed ajax yet,
but I have confirmed that 1.44 works on 'certain' disk types. Anyways,
in opening up the machine, I found 1 very thin black and one very thin yellow
wire which were soldered to a pins of an IC that ran from under the
floppy drive to over near the power supply. Apparently an afterproduction
fix. But since I have one of the 'odd' machines I was wondering if
everyone else with older and/or newer machines have these 2 small wires running
from IC pin to IC pin (both ends of both wire soldered directly onto one of the
pins on the particular IC chip.

The WD1772 and the Ajax (which replaces it) are under the host adapter. There's one screw on the lower-left corner (I think) of the board that must be removed, and then the board comes out. The Ajax chip doesn't say Ajax on it; I was surprised. I don't remember what it says; it's inside my machine now. :^)

2463. Is GCC 2.1 with PL20 mintlibs suppose to fail tests?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-22 18:04:14 UTC
From: chu@acsu.buffalo.edu
Message-ID: <Bq9E72.MGA@acsu.buffalo.edu>
Source record: 43761

Hi,

I'm pretty sure that I have all relevant files and that they are all in the right places (i.e., no complaints of missing files). I made and ran all the tests that were in /atari/gnustuff/tos/gcctest/tests03.zoo on atari.archive (The make went relatively without a hitch. The only problem is that apparently the HSC make (the only one I have) doesn't do command line passing the same way mintshel does, so make works fine if I start it from the desktop but not from mintshel.)

However, somewhere between 5 to 10 of them failed (I have the details of which tests failed and what the diagnostic was at home. I forgot to bring them with me. If they're important, tell me). Now, using GCC 2.1 and PatchLevel 20 of the MiNT Library, is this suppose to happen? In other words, do I have anything to worry about? If so, what did I do wrong?

Thanks,
john

You know another odd thing... is on the disks that I CAN get to format
to 1.44 megs on the above machine, at about the 40th track the drive head
travels somewhere and back before continuing on... unlike the rest of the
disk. This same place seems to be where the memorex disks error in formatting
at 1.44. What is it that is 'magical' about the 40th track, and Tos
2.05 with 1.44 drive? The mystery gets deeper, and more confusing.

> about to be redrawn before I call my display procedure?

I think, you want to swap the screen at every vertical sync. In this case, your (slow) eyes see a (flickery) mixture of both pictures (I used this in a grayscale viewer).

There are two ways:

- You load the two screens in two areas screen1 and screen2 and run a program similar to the following (I do not know the exact bindings of Personal Pascal):

```
while true
do begin
Setscreen( screen1 );
Vsync();
Setscreen( screen2 );
Vsync();
end;
```

You need the Setscreen() to switch the screen. The screen is activated at the vertical sync. You need the Vsync() to prevent the switch to the other screen before this screen is fully displayed!

If you want to do some additional computations, you should insert them before the Setscreen() call. But this computation should not need too much time!

- Add your own trap-routine for the vsync interrupt, which changes the physical screen system variable (I think the name was _phybase, but I don't have any documentation here) every call and then jumps to the original vsync interrupt routine.
The original routine moves this address into the shifter and the next screen shown is changed.

With this method, you have no time constraints for additional computations, because the swichting runs 'parallel' to the user program.

Sincerly

Uli

I haven't noticed one in any of these palces (&I took the WHOLE thing
apart at one point :-).

What it looks like is something out of Darwin. Instead of going
directly from a megaSTe w/out the AJAX, 1.44meg drive & TOS 2.06 to
one with these parts Atari seemsto have released each step along the
way. Each different setup appears to show a different part of the
production process/ assembly line being changed over.

>NONE of the external floppy formatters will work (at 8mhz or 16mhz) format
>correctly at 1.44. Is THIS a 2.05 bug?

I also have TOS 2.05 and a 1.44 drive. Using the formatters of Neodesk III
and DiamondBack II, I have found the following:
-the DB accessory formatter does not work at all from the desktop
-formatting works fine in both normal and extended densities
when running DB
-the DB accessory formatter works fine in both normal and extended
densities when run from Neodesk III.
-Neodesk III's formatter works fine in both normal and extended
densities (can only be run from Neodesk)
I haven't tried the accessory from any other programs yet, but I would
guess that it would probably work. It seems that something about the
TOS 2.05 desktop interferes with "external" formatters. Has anyone else
had similar results?

> On my MSTe the only dip switch up is 7.

Same here. I read on the net a while back that switch 7 indicates
a HD drive, and the rest are "reserved for future use." Anyone know
if this is correct?

I have a "megafile" 20Meg SH204 (?) hard disk, left over from my old 1040St.
I would like to add it to my Mega4Ste. What has to be done?
Should the dip switch be set to 1? Does it have to be re-formatted?
Where should it be plugged in? Thanks for any info.

What I do to transfer files for/to my ST from a MAC is to format a disk
DD on a MAC (same for MS-DOS) but NOT on the ST.

Under MS-DOS : copy the files you want to transfer on the ST onto the
disk. To tranfer files form ST to MS-DOS - do the same
thing on the ST.

Under FINDER : Use the file conversion utility provided with the MAC to
transfer the files on/from the disk.

I hope it helps

Perhaps the track-seek-time is too short, maybe you should try it with a
6ms seek-rate? When the controller runs at 16MHz, it will 'seek' the tracks
twice as fast... Who knows!

mint.cnf is not meant to start process'. It's purpose is to configure MiNT
at boot time so that things such as links in U:/ exist and tell MiNT whether
to use HARDSCROLL etc.

To do what you want to do you'll need to run a shell (probably called
init.prg and in the same directory as mint.prg) which starts up your
processes for you, then either starts another shell or starts GEM.

Steve

PS. If you don't need GEM and you like your machine to look like a Unix box,
may I suggest you aquire my Unix-like init(8) package from atari.archive.

I know nothing about Waffle - does it send QWK mail-files? There are several
QWK mail-readers for the ST.

- The St can read/write standard DOS disks
- A PC can read/write standard DOS-disks :)
- The Mac can read/write standard DOS-disks, if you use an Init such as
PC-Access or DOS-mounter.

Guess what the solution is...?
Format your disks as DOS-disks, either on a PC, or on the ST, with a special
DOS-formatting program (several of these can be found at atari.archive), or use
one of the Inits mentioned on the Mac to format DOS-disks (provided the Mac has
a SuperDrive). This way you're able to transfer files form PC <-> ST, PC <->
Mac, ST <-> Mac. I do this often, without problems.

>
PC-ST/ST-PC

For one you can format your floppy on a PC - no problem for the atari
to read that format.

You can also use one of several formatting-progs on the atari, which
format PC-disks.

Then you read/write your files on the cmputers as usual.

The only real difference between a MS-DOS disk and an ATARI disk are a few
bytes in the bootsector. There is also a different byte in the FAT, but
most PC aren`t so fussy about that byte that you would have to worry.

MAC-ST/ST-MAC

Dunno.

You need to make a symbolic link; try:
ln -s c:/bin u:/bin
(the "-s" means "symbolic link"; without this it tries to make a "hard"
link, which will fail on TOS drives or on drive u:).

Oops, as was pointed out to me, Diamond Back does format correctly
on this setup. The only problem is that the show information will
say that only 1 meg is free when using a high density extended format
(the Neodesk show info says that there are 1.6 total bytes
but 1 meg free right after formatting). Other than that it works fine.
Sorry about the misinformation, and thanks to everyone who responded to
my post.

2483. RAMdisks

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-23 17:02:47 UTC
From: glens@natinst.com
Message-ID: <1992Jun23.170247.29272@natinst.com>
Source record: 43785

Well, I finally have 4 Megs of RAM in my STe. I have been using the RAMdisk that was supplied in the Developers Kit from Atari set at 600K. But the other day I tried changing it to 2000K (2 Meg) and it assembled fine (using MadMac) but it would not operate properly at all. It would munge files and report an astronomic amount of free space under 'Show Info'. Is there an upper limit on the size that that RAMdisk can handle? How large have people successfully used this RAMdisk? Or is there a different RAMdisk I can use around the 2 Meg mark?

Thanks.

2484. Hard disk help (please)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-23 19:03:04 UTC
From: dbsuthe@pbhya.PacBell.COM
Message-ID: <1992Jun23.190304.9734@pbhya.PacBell.COM>
Source record: 43787

THE PROBLEM:
The xcontrol.acc causes the ST to bomb (two bombs usually) when I
boot the ST. This happens even when the only thing on the hard
drive is : xcontrol.acc, the standard CPX files, control.inf and
the icdboot.sys.

THE CONFIGURATION:
1040ST 1MEG with either TOS 2.06 or 1.4, -or- 1040STe with TOS 2.06,
and either ICD adSCSI or Supra (early) interface
and either ICDBOOT, AHDI5.0 or SUPBOOT (hard disk driver)
and Seagate ST157N (50meg) hard disk.

OTHER SYMPTOMS:
The control panel sometimes works, if there is only one or two CPXs
loaded.
No error messages are reported by the ICD driver.
It often does not load the first CPX shown.

SUSPECTS ALREADY CLEARED:
CPU (Tried on 3 systems)
Software (Same files work fine on my Mega 44 drive with either CPU)
Interface hardware (Supra and ICD tried)
Format incompatabilites (the disk has been reformated with each driver)
Viruses (My virus checkers show no problems)

OTHER SUSPECTS:
Disk drive hardware options (I have no manuals for the drive)
Disk drive format options (interleave = 1...)
.
.
.

I would appreciate any help that anyone might have. Thanks.

Well, I still am not able to get a reliable format with 2.05, ajax,
and 1.44 in my MSTe... Diamond Format will say it formatted fine, but
anytime I try to copy any files to disks formatted with it, I get random
errors on every disk. I then scanned the disks... got 'bad sectors' at varying
places. And these are HD disks, and new, and from 2 different brand name manu-
facturers.
Arghh... guess I might have to check that I did the power supply fix
correctly, as lately it seems to be getting even more random in where the
errors occur.

Mmmh, basically the same approach.

>> reached_it = 1; /* must be there before the VBI */
>> while(reached_it); /* burn up leftover cycles */
>
>It seems like this part of your code is doing the same thing Vsync is.
Not quite, since with Vsync() you might wait an extra VBI under very dire
circumstances. The concept is the same, but putting in Vsync() there
wouldn't be as good.

>
[Stuff deleted]

>Note that the vsync call is a call to the routine given above. This
>works on all versions of TOS and never produces flicker. Getting
>the Setscreen and vsync calls out of order will cause flicker.

I see that it won't produce flicker and I also see that in usual
circumstances you are not wasting time, so basically both of my comments
about Setscreen() and Vsync() where disproven.

Personally though I don't like this method, since I don't see how you get
clock work precison flick rates. The time the screen is flicked may wobble
from 1- _vcount in the worst case. It won't do that under normal circumstances,
but circumstances aren't always normal.

My problem before I did the VBI code was that in order to do the Setscreen()
at the precise moment, I needed to check FRCLOCK to turn over.
Then doing Stscreen() and Vsync(), I lost one VBL. That's why I said using
Vsync() was not a great idea.

>production process/ assembly line being changed over.
>
What it looks like to me is the "usual" effects of a part supplier change
that happens in most large production situations where there is alot of
"old stock" still in the plant: you continue using "old stock" until it
is consumed, then begin replacing it with "new". Different parts run out
of "old stock" at different times. There may also be a short period when
final assembly happens in many different combinations of "old" and "new"
assemblies from the way "old" and "new" style assemblies are placed in stock
after board level testing, and issued from stock to final assembly.

Very common practice with commercial electronics, it minimizes the amounts
of "old stock" that must be scrapped (disposed of at a loss). Most
consumers will never even notice it.

Very uncommon in military electronics, usually prohibited in the purchasing
contract since most part/design/configuration changes must be individually
approved by the customer (the military) in these contracts.

Not very common when "just in time" production methods are used either, as
no large stock of any part or assembly is ever maintained.

From: dstailey@leidecker.gsfc.nasa.gov
Message-ID: <DSTAILEY.92Jun23214604@leidecker.gsfc.nasa.gov>
Source record: 43844

ENOTDIR is missing from errno.h in patchlevel 20 of the MINT libs.
In errno.h, it is only defined if __MINT__ is not defined. If ENOTDIR
was intentionally removed, what should I replace it with when porting
BSD-compatible code?

Sorry ...
I'm sure, I also tried ln -s and got an error message. But it seems, that
I must have made another error. Just two minutes ago, I tried it again
with `ln -s' and it worked.

ECHILD is also not there.. very useful with wait() :-).

Steve

PS. Wouldn't it be nice if the standard Unix compatable library routines
returned the Unix standard error codes. I remember even lattice C on the
Sinclair QL did this.

>of Atari STs. The floppy's sender unfortunately has no modem.

To transfer to the Mac:
Fire up Apple File Exchange on the Mac. Format the disk as DOS 800K. Write to this disk using the ST

To transfer to the PC:
Format disk on the PC (using FORMAT /n:9 /t:80). Write to this disk using the ST.

Date: 1992-06-24 11:08:27 UTC
From: PAULETTI@biel.be.tech.ascom.ch
Message-ID: <1992Jun24.110827.487@hasler.ascom.ch>
Source record: 43846

I am writing a utility to setup my DeskJet 500. For that reason I want to
enquire if the printer is on or of.
When I use the GEMDOS function Cprnos I always get the return value -1.
Using the BOIS function Bcostat(0) returns the same value.
How do I get this work ?

SYSTEM : TOS 1.0
Compiler : Pure C

Is the problem perhaps not TOS, is it the HP interface of the printer.
I have heard, that there is something strange with that but I could not
find any exact information about it.

cheers andreas pauletti

2495. Dominion v1.06 on the ST/TERMCAP

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-24 12:44:27 UTC
From: yannikos@vmars.tuwien.ac.at
Message-ID: <1992Jun24.124427.2420@email.tuwien.ac.at>
Source record: 43847

Yesterday I ported Dominion 1.06 to the ST running MiNT/GCC 2.1...
After some minor changes, it compiled correctly, but when I started
it I noticed that some of the wmove() calls were not working
correctly. wmove(w,x,1) for example should have moved the cursor
to the beginning of line x, but it was simply ignored - the cursor
remained where it was before... Is this a known bug in the curses
library (or termcap) or does this sound as if my TERMCAP file
has wrong settings for 'st52'? Apart from some line-clearing
commands, everything else worked fine (reverse video etc.).

Any hints?

Marinos Yannikos

PS: Since I'm rather new to curses/termcap stuff, I might be wrong
in my assumption that wmove() is a call in curses.olb ...
I hope not! :-)

An Ajax/HD disk in either a MegaSTe or TT is very susceptable to noise
eminating from the power supply. If you do not have the cables routed
exactly correctly then you will have random formatting and read/write errors
that may or may not be detected by the operating system.

The installation instructions contain detailed instructions on cable routing,
I even had to add extra sheilding around my internal cables before I could get
reliable high density operation. In addition, some TT's & Mega STes' require
that the center grounding screw within the power supply be removed to reduce
the noise that interfers with HD drive operation. Newer models are being
shiped with this grounding screw removed.

2497. Immediate addressing in Laser C assembler

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-24 17:01:54 UTC
From: gt1448b@prism.gatech.EDU
Message-ID: <61849@hydra.gatech.EDU>
Source record: 43850

Does anyone know if the assembler in Laser C v2.1 can handle
addressing modes like this:

```
asm {
MOVE.L #string, D0
.
.
.
string:
DC.B 'Whatever',0
}
```

I get an illegal numeric constant error message from the compiler
when I tried this. Since the compiler does relocatable code I would
think it could handle this.

there is some sort of bug in curses/termcap for GNU C. i ported sc 6.8 (spreadsheet) but have also had some problems with cursor moves (moving the cursor over a blank line did not reposition the cursor correctly and left weird artifacts, tho moving over non-blank lines is fine). i tracked down the code in sc where the problem occurs and it runs fine on a BSD/POSIX system. i have not had a chance to look into the GNU curses/termcap lib (i have a recent copy, i believe). but i do believe it is either a bug or a bad configuration. it might need padding in the termcap entries (untested since i just thought of that this instant). i assume the GNU termcap lib (correctly or reasonably) handles padding. i have faith in the team of bammi+smith... :-)

if i find the time to track this down, i will post sc-6.8.

good luck...

I had a similar problem using curses on UNIX the other day. I turned out I had called cbreak() before initscr() by mistake: cbreak() must be called after initscr(). Also, I think the column numbering starts at zero (although I could easily be wrong).

2500. Help needed running MGR with MiNT 0.94

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-24 20:37:38 UTC
From: mboening.pad@sni.de
Message-ID: <mboen.709418258@offbeat>
Source record: 43854

Hi there,

this may be a stupid and/or frequently asked question, but what the
heck:

I've got MiNT 0.94 running on a Mega ST 2 with 2 MB RAM (no extension)
and a Vortex Sideloader removable disk. Recently, I got mgr for the ST
which is supposed to run with MiNT 0.6 or higher. Well, it starts up OK,
I guess. I get the nice sign-on screen and then the blank desktop with
the mouse cursor. However, there's no icons (can I configure them?).
More important, and this is the real question: When I try to open a new
window in that nice little pop-up menu, all I get is the message
`Can't get pty'. What's happening. Not enough RAM? (MGR is supposed to
run with 1 Meg) Or something missing in the configuration that I should
check for?

Thanx for any help.

So long,
Martin

I am going to be adding a 1.4 meg floppy to my ST system. In regards to the drive mechanism, does it matter which brand I use? I remember some discussion about some 720k drives having trouble recognising disk swaps. Does this problem exist for HD drives also? Thanks.
Note that the drive faceplate does not matter to me. I just need a drive that is functionally compatible (given the appropriate controller modifications, etc.).

2502. Emacs

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-25 04:07:45 UTC
From: mintha@geog.ubc.ca
Message-ID: <1992Jun25.040745.18792@unixg.ubc.ca>
Source record: 43856

I have just finished setting up a complete MiNT/ Gnu C/ Emacs
system on my atari, and I thought I would share some of the problems
I have had (as well as ask a couple of questions!)

First, this may be common knowledge to everyone else, but I was
surprised to find out that the mint version of Emacs 18.57 supports
the 'shell' command, so you can run a couple of shells in buffers
inside emacs (thereby never having to leave emacs!) Unfortunately
the arrow keys don't work properly with this version, however the
xkey program, will let you redefine the arrow keys to the emacs
commands (^f ^b ^p ^n) I haven't figured out how to get the function
keys to work yet - anyone know how I can do this?

I set up tcsh as my shell. The file TCSH.ZOO has all you need
except the utilites (i.e. ls, cat, etc.) I picked up the following
which gave me most of the unix utilities:
FUTILBIN.ZOO PSTOPLS.ZOO, LESSBIN.ZOO, TEXT11B.ZOO, AKPUTL7.ZOO

If your setting up GCC 2.2.* you will need the following files:
(The version numbers have probably changed) (I have shown the directories
that I have put them in)

GCC21B02.ZOO - binaries of GCC compiler/assembler/etc. (D:\GNU\BIN)
INCLUE80.ZOO - Include Files (D:\GNU\INCLUDE\GCC)
GMLIBO23.ZOO - Gem libraries (D:\GNU\LIB)
LIBOLB80.ZOO - Gnu Libraries (D:\GNU\LIB)
UTLBIN27.ZOO - Rest of binaries for GCC (D:\GNU\BIN)
PMLOLB18.ZOO - Math libraries (D:\GNU\LIB)
GPINCL07.ZOO - G++ include files (D:\GNU\INCLUDE\G++)
GPLIBO07.ZOO - G++ libraries (D:\GNU\LIB)

and you also need the file crt0.c from the source for the gnu library
GMLIBS23.ZOO and compile it to crt0.o with: gcc -c crt0.c

I use tcsh as my shell, and have the following environment variables
set, to allow gcc to work:

```
setenv GCCEXEC d:/gnu/bin/gcc-
setenv GNULIB d:/gnu/lib
setenv GNUINC d:/gnu/include/gcc
setenv GXXINV d:/gnu/include/g++
setenv TEMP d:/tmp
setenv TMPDIR $TERM
```

(note I use the forward slashes, because that is what tcsh expects)

This should be enough to compile using GCC.

Hope this is of some help to someone. and please let me know if I
am missing anything important (such as the little utility that makes
my 8 MHz Atari run at 50 MHz!)

Jim

There is a bug at least in TOS 1.04 known, perhaps that it is:
The AES don't initialisize all variables, so when the fastload-bit of
the physicaly first ACC is set, these variables are not set to zero
and the AES crashes sometimes. I don't know if that is fixed in newer
TOS-versions.

I tried this; it worked OK, but you probably need a TT to really appreciate it.
I wrote a small utility for running a shell via the serial port(s); if anybody
is interested, I can post the source.

2511. Re: Dominion v1.06 on the ST/TERMCAP

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-25 17:40:33 UTC
From: rosenkra@convex.com
Message-ID: <1992Jun25.174033.27413@convex.com>
Source record: 43862

yesterday i claimed that curses/termcap (GNU) had a bug since i could not get sc 6.8 to run properly. while i still think there is a bug (rather than a feature), i did manage a workaround. i claim it is a bug since you should not have to do what i describe below.

setting UNIXMODE to include the "b" option made things work. i also discovered a bug in sc itself, tho i am not sure this had an impact. there was an errant "move(x,y)" which should have been "move(y,x)".

so, i have included

```
...
#include <stdio.h>
...
#ifdef atarist
/* "atarist" is defined by gcc 1.40 */
int __default_mode__ = _IOBIN;
#endif
...
```

as a global in the code to force all streams to be binary. this makes it possible to run and not have to worry about the environment. oh, i am using the MiNT libs PL 19. note that it is not sufficient to call _binmode() as the std{in,out,err} streams are already setup by the time you get to your main. i don't think you can do this if the code calls _binmode(), tho. you will probably get a double definition error from the linker since binmode.c also declares __default_mode__ global (and not external). it might not be a bad idea to put this symbol in a separate file, provided it is in a .olb (so it won't be searched for by ld unless needed).

the global insures that the standard streams are also binary since _main() does essentially:

```
stdin->_flag = ... | __default_mode__;
...
```

long before it calls your main(). note that the scope of this force to binary mode is probably all child processes spawned from the program. in particular, sc is able to invoke a PAGER and has a shell escape (ie !). i am not sure what impact this may have. once sc exits, however, and in the context of the invoking shell, this mode change _should_ have no effect (parents don't inherit their children's handles).

i am still not sure why this fixes the problem, but am satisfied that it does (fix the problem). this may also explain why it starts accepting CR as LF (instead of having to type ^J directly). it may also explain why i have had problems with fscanf(stdin,...) in the past. i suppose i should

look at GCC/MiNT gnu.olb's stdio stuff for enlightenment.

for more info, check the lib source (files binmode.c and main.c).

so i guess i will post sc 6.8 soon after i get a chance to test it on
something more substantial than the tutorial.

man, i LOVE GNU C/MiNT/tcsh!!! i can count the changes i made to this code
on one hand (most are trivial like y.tab.h -> y_tab.h).

From: bpat@cs.mcgill.ca
Message-ID: <1992Jun25.181342.2971@cs.mcgill.ca>
Source record: 43864

The problem is that *new* TOSes (Starting from the latest 1.2 in late STfm's, the one I've got) don't wait for mouse release when scrolling windows. It just keeps on sending scroll events to the application. If your program is fast enough (Or if you've got more than 8Mhz !!!), then you, the user, cannot let go of the button fast enough, and the computer has time to send 2 or more scroll events !!!
Best way is to ignore scrolls until the event buffer is empty, and then accept one more until it's empty again, and so on. This does not mean you must ingnore ALL events. Just scroll events.

Patrick BETREMIEUX.

Thank you for your reaction to my original posting. I agree with the solution:
I have succesfully implemented a similar algorithm, although I only ignored
scroll events until any other event.

An other solution is to wait in evnt_multi() for a *double* mouse-click.
This *delays* the sending of subsequent scroll events, instead of preventing
them, and thereby you still have auto-repeat scrolling at a reasonable
pace. This is much simpler to implement, but has as disadvantage that all
reactions to mouse clicks are delayed until the double click timeout has
expired.

I had a similar problem some years ago as I tried to put a real time clock in my ST (just plug in the keyboard processor slot). Everything worked well apart some keys ine the numeric keypad.

The answer was quite simple: bad contacts.

Try to wipe the 40 pins of your keyboard processor (with alcohol or anything better)..

2523. Help needed with ST boot.

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-26 15:46:49 UTC
From: dud@cbnewsf.cb.att.com
Message-ID: <1992Jun26.154649.6285@cbfsb.cb.att.com>
Source record: 43873

I have an early 520ST that boots TOS 0.8 (I think) *from disk*.
It has 6 ROM sockets, but only has 2 of them populated with the
minimal boot ROM's that came in the early ST's.

I have gotten TOS1.4 ROMS, and upgraded the machine to 2Meg of RAM.

My question is this:

What is supposed to happen when you power up the ST, when you have
ROM TOS 1.4 ? (Assume no hard disk). Must you have a floppy inserted
in drive A:? Is the desktop supposed to come up even if no floppy is
loaded? If a floppy is loaded, what does it need on it for TOS to "boot"
properly? (I understand that optionally, you can have .ACC's and stuff
in the AUTO folder, but I'm not interested in that right now.)

I can boot my disk TOS 0.8 from floppy with the new ROM's installed,
but nothing useful happens if I power up with no floppy loaded, or
a floppy loaded that has been formatted on my IBM clone.

Is anything special supposed to be in the boot record? How do I put
it there?

Thanks in advance for any help you can give me. I'm really stuck.

I've had to repair two which showed similar symptoms. The problem both times was a dry joint on one of the wire links. The problem is that you have to unscrew the few thousand screws holding the thing together. If the rubber cups fall all over the place & you count up and find one seems to be missing it probably isn't.... the RETURN key usually has two cup slots but only the bottom one is used.

When your TOS1.4 is installed correctly, the machine should power-up without problems, i.e. you should get the desktop without there being a special floppy in the drive. There's even no need to have a floppy at all in the drive, althought powering up then may take longer and the floppy-light will stay on.
This still dates from the floppy-TOS: the new TOS's still start to look at the floppy to see if there's a TOS on it (I think - correct me if I'm wrong), and switch to the ROMs if they found nothing 'usefull' on the floppy.
So putting a plain formatted floppy in the drive should be enough - also IBM floppies should do (since the ST is capable of reading DOS-disks). You may try to put a ST-formatted floppy in the drive, although I suspect it won't make any difference.
Well, I'm afraid this doesn't solve your problem, does it? I'm sorry...

2527. TT fastram upgrading from 4 to 16 MB

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-27 14:23:20 UTC
From: micha@moko.saar.de
Message-ID: <H.h9htBskJ2a6@moko.saar.de>
Source record: 43882
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I've a problem upgrading my TT fastram board from 4 to 16 MB. It's copyright Atari Corp., No. CA401058-001 Rev. B. All SIMM modules are in sockets.

I've changed all modules from 1 MB * 8 Bit to 4 MB * 9 Bit, the pins for Bit 9 are not connected. The jumper settings are:

```
W W W W W W
1 1 1 1 1 1
0 0 0 0 0 0
1 2 3 4 5 6

F F R R F F
```

F = front, R = rear

W103 = base address is set to 0x1000000
W104 = dto.
W105 = burst mode disabled
W106 = controler is set to 16 MB (instead of 4 MB)

This configuration works fine on old and new TT versions. But in some cases, there are bus errors or more bombs. Some programs which work in 4 MB mode, don't work in 16 MB mode, some other get problems everytime in the same situation.

The memory check (TOS 3.06) accepts the 16 MB configuration.

The chips on SIMM modules are NEC 424100-70.

Any ideas???

>remove some more bugs..

Roger, you in fact can need the folder fix on 1.4. While the folder
pool handling is better, it is not fixed 100% and the "out of memeory"
warning does not always show up before damage is done. I have 1.4, and
100 meg of Hard Drive, and rarely turn the computer off, and I use
128 extra folders. Before doing that, I had the same problems as I had on
1.0.
So just saying you don't need it is dead wrong.

2530. Developing Tools you use...

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-28 21:18:15 UTC
From: aa596@cleveland.Freenet.Edu
Message-ID: <1992Jun28.211815.27937@usenet.ins.cwru.edu>
Source record: 43883

To all:
I am compiling a list of development tools that are being used on the ST,STe, and TT systems. This list is being compiled for the Cleveland Freenet - a public access information system. I am a co-sysop of the Atari Forum, with my general responsability being the Programming and developers forum. So, what I would like to know are the following:

1. Compilers/languages that are being used

2. Editors that are being used

3. Assemblers being used

4. Tools - Piblic domain, comercial...

5. The books you find most useful.

6. and any comments you may have in general.

If possible, reply via e-mail to aa596@cleveland.freenet.edu. I will post my findings here, and also in the Freenet programmers forum.

Thanks in advanced...

PCH

r>there is some sort of bug in curses/termcap for GNU C. i ported sc 6.8
r>(spreadsheet) but have also had some problems with cursor moves (moving
r>the cursor over a blank line did not reposition the cursor correctly and
.....

I found 2 faults in curses/termcap so far:

1. Newline if not mentioned otherwise in termcap will be achieved by cr
which the Atari vt52 incorrectly realises by cr/lf. The addition of

<TAB>:nl=\EB:\

will make the Lib use ESC-B instead of cr.

2. if moving right, the crput(?) routine uses TAB's if the distance is
greater then 8. Look for the line

#define HARDTABS 8

and increase the number to anything larger then screenwidth. Tabs are then
not used.

Kai.

2532. Re: Help! Transfer ST files to PC or Mac

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-28 23:59:33 UTC
From: kawakami@ocf.berkeley.edu
Message-ID: <44441@ucbvax.BERKELEY.EDU>
Source record: 43884

TIP!

Use good disks, and format them on the TARGET machine, not on the system where the data originates. As the others have said, the ST can write to DD PC disks.

Why should you format on the target machine?

For PCs, it will ensure that the PC can read the diskette, since some MS-DOSs are rather "inflexible" about the FAT sizes, etc.

For Macs, the recording methods differ, and you have to be sure that the drive can read the diskette. Sometimes, a disk which works in PCs and STs won't format as 720K DOS on the Mac, and vice versa in all directions.

>and PC experience, but none of the folks around here have any knowledge
>of Atari STs. The floppy's sender unfortunately has no modem.

I don't think Murray has access to an ST.
If so then using a PC disk editor he should edit the first three bytes
of the disk boot sector to read:-

EB 34 90

If that doesn't make it PC readable then the disk is probably 10SPT.
In which case put:-

DRIVPARM = /d:1 /s:10

in your CONFIG.SYS file. This allows the floppy to read 10SPT disks.
I dunno why but if I put /d:0 it doesn't work.

However if all else fails find an ST and follow the other suggestions.

>
> Bill Dudley

You don`t need a disk in your floppy to boot even though it might take
a while until the desktop appears. Using a floppy speeds the procedure
naturally up. Using a Disk-TOS will eventually bring your ST to boot
the Disk-TOS, even if there ROM-TOS is available.

Your problem (I think) is the following:

Some (one) chip might be loos in its socket or if you fooled
around a lot with cables, one of these might not contact correctly.
I had a similar problem when installing TOS1.4 with TOS1.0 with a switch.
I my case it was a cold soughtering (sathering ? don`t know the correct englisch
word for (german) l\"{o}ten) spot.

You might have to use a current tester or something similar to see if
everything there is ok.

stay cool, :-)
my machine just gave up it`s soul last night :-(
dunno yet what it is.

2537. Emacs, MiNT and other goodies

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-29 15:03:53 UTC
From: monnier@disuns2.epfl.ch
Message-ID: <1992Jun29.170353@disuns2.epfl.ch>
Source record: 43792

I recently instaled MiNT, tcsh, Emacs, etc on my small Harddrive.

I do have a little question:
I tried to dump the emacs, but without success. Since then, I noticed
that the emacs bin is executable.
So what is exactly this dumping process ('dump' doesn't tell me a lot)
Does it give me back some Kbytes (the 500K of Emacs are not very nice
especially when tcsh is running and I don't even mention mgr) ?

Further more. my Emacs only accepted to start after I put the content
of the termcap file in the TERMCAP variable: the path was not sufficient.

Is it possible to run 2 or 3 times tcsh (or anything else) without having
2 (or 3) duplicates of the same code in memory. It is not possible with
TOS but maybe under MiNT ...?

Message-ID: <1992Jun29.151359.8740@natinst.com>
Source record: 43791

Am I wrong or can your virtual screen only be about 4 times as wide
as a normal low-rez screen? I am refering to the 'LINEWIDTH' register in
the shifter (offset $FF820F). I believe it is an 8 bit register which means
the maximum number of 'extra words' after a scan line is 255. In low-rez
one scan line takes 80 words. 255 / 80 = 3.1875. I have hardware scrolling
working but I would like a larger virtual screen.

Thanks. (I hope I didn't just violate my non-disclosure agreement)

2542. Cross-GCC for Minix?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-29 20:35:18 UTC
From: stenny@troja.stgt.sub.org
Message-ID: <0874.06.92@troja.stgt.sub.org>
Source record: 43806

Hi!

I wonder, if I can find a GNU-C cross development system, to compile C
programs for Minix under my usual TOS environment.

I suppose, I could use the standard TOS gcc-cc1 to compile and the normal
gcc-as, to assemble the files. But I would need another gcc and a gcc-ld,
which supports the Minix load format for executable files.

If poolfix92.lzh is on aa, it may still be in new, which means
you can't see it, but you can download if you know the correct filename.
As to poolfix and foldernnn, they fix 2 seperate probles, as far as
I know. As has been stated often enough that it deserves a place in the
FAQ (hint, hint), TOS 1.4 still requires foldernnn, or some fix, if
you have a large hard drive, access a lot of folders, and other situations.
TOS 1.4 should put up a warning and let you know, but my experience is that
this is not always the case.
I run a small usenet site, where every group name is a nested group
of folders, and article counts run aroud 300. I use 128 extra folder slots.
On TOS1.2, I would hve needed over 300.

Some people claim to run bbs for months wioth no extra folders and
no problems, however, I figure for the small ammount of memory the fix
takes, why take chances.

Also, though the bug fixed by poolfix was supposedly rare, and
unlikely on 1.4, _everyone_ I know who has upgraded to 1.4 has hit
it and had to install poolfix.

This program was posted on GEnie has the full source code for all versions,
(no use to these Unix freeks as its all assembler :-)) the Atari version
and Claus Brod's one and the New 92 version, and all the bugs are fully
commented...

I you would like me to post this on A.A...

My statments about FOLDERFIX is that a lot of people here state that it is a
MUST, that is not correct, I run TOS 1.4 and don't use it...

As you have stated its a MUST under some circumstances, but then they are not
always made clear, and Atari do state that it will not corrupt your
hard drive if you don't use it..

At one end of the drive you will find a bed of nails, twin row of pins,
this is next to the 50 way SCSI connector,
there are pair of pins marked P NC 4 2 1, I don't remember from which end,
but a jumper has to be fitted to the P pair to enable parity...

So if there is no jumper fitted at all then you have device 0 and No parity.

Before you do this you will have to E-Mail,

wmagro@roma.uiuc.edu (William Magro)

: I recently instaled MiNT, tcsh, Emacs, etc on my small Harddrive.
:

I lastly managed to do a dump of Emacs 18.57. Badly, it is even bigger than before. But at least, I have understood what was that dumping ! (the trick to do the dump was to change some file names in loadup.el so that they aren't bigger than 8 chars and are only in lowercase).

For TERMCAP, the trick has just been posted a few days before (but I only read it yesterday): just have to remove the CR/LF on each terminal description. So each terminal decriptor has to be on one line which is not very nice. I feel that the problem is just that Emacs only accepts Unix eoln that means only LF and not CR/LF. I will check !

finally, one question remains: I heard about UNIXMODE but I still can't understand what it represents, ...: what should be in there (examples are not very clear: why rCLAHbd,./ ?).

2550. strftime() in gcc library---it works.

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-30 08:21:21 UTC
From: neuhaus@vier.informatik.uni-kl.de
Message-ID: <neuhaus.709892481@vier>
Source record: 43803
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hi.

I have recently posted an announcement for my port of ash, a
Bourne-compatibe shell from 4.4BSD, for MiNT. In my blurb, I
apparently said several things which may be easily misunderstood.

* strftime() isn't standard

That's not true, and I said so. I said that strftime() was ANSI, but
that the GNU date manpage mentioned several POSIX extensions. When I
wrote this, I had the relevant section of the ISO C Standard before
me, and either I'm blind, or there are really some formats featured by
POSIX, but not by ANSI. :-)

* strftime() can't be kicked out of the library

This can't really be true, because the only entry point that the
strftime() module defines is---strftime itself! The linker gave me
errors when I tried to compile GNU date, and I remember it choking on
strftime(). Must have been a weird setup, then.

* strftime() behaves illegitimately on undefined formats

This is not true, because the Standard itself says that the bahaviour
is undefined in such cases.

I would like to thank Michal Jaegermann for pointing out these errors
to me.

From: neuhaus@vier.informatik.uni-kl.de
Message-ID: <neuhaus.709893388@vier>
Source record: 43802

Also, the MiNT libraries' using ENOENT for ``No such process'' made me
change an error message in ash to:

```
% foo
foo: No such file or directory (or pid)
```

Looks funny. :-) Our UNIX system has ESRCH for this.

Nontheless, MiNT/gcc is a *very* fine combo, and I would like to thank
all who contributed. I think we all owe them a lot.

> So what is exactly this dumping process ('dump' doesn't tell me a lot)

It's the process by which the standard LISP files get preloaded into Emacs.
This saves a *lot* of start-up time.

> Does it give me back some Kbytes (the 500K of Emacs are not very nice
> especially when tcsh is running and I don't even mention mgr) ?

No. You just gain time, not space.

> Further more. my Emacs only accepted to start after I put the content
> of the termcap file in the TERMCAP variable: the path was not sufficient.

Check if you have any CR characters in the termcap file.

> Is it possible to run 2 or 3 times tcsh (or anything else) without having
> 2 (or 3) duplicates of the same code in memory. It is not possible with
> TOS but maybe under MiNT ...?

I fear that MiNT doesn't (yet ?) do this ...

From: rdjeline@cip.informatik.uni-erlangen.de
Message-ID: <BqnnFw.GK5@immd4.informatik.uni-erlangen.de>
Source record: 43804

Well 64MB of Ram is quite nice. But there should be a "little bit"
more of CPU-Speed in such a Computer, shouldn't it ?

There's one solution for the old TT's (those who have an Daughter
board.) The CPU and FPU are asynchronous clocked with 32 Mhz, while
the System is running 16 MHz :-(And Now: The CPU and FPU are new
and run 50 MHz. The Speed-Up is worst case: 35%.

Of course, the CPU and FPU are turning Wait States. But I hope the□
technicians manage to give it a BIG Cache. (sooner or later).

Ciao

2555. MIDI interrupts and buffers...

Newsgroup: comp.sys.atari.st.tech
Date: 1992-06-30 16:31:54 UTC
From: joeg@praven.gsf.dec.com
Message-ID: <JOEG.92Jun30113154@praven.gsf.dec.com>
Source record: 43811

Anyone have a clue how to write an interrupt routine in C (Turbo) that will get called whenever something comes in the midi port? I'm perfectly happy with the internal routines to handle midi i/o, I'd just like the interrupt chain to get around to calling my code (safely).

Also, clues on how to set larger midi buffers would be helpful. I'm thinking of something where I'd like to have multiple buffers, etc.

Is there anyway to determine how large the current buffer is?

Please mail to me (unless there is general interest), thanx.

Joe

>
> [about problems with curses and text-mode streams]

There probably is a conflict between curses' notion of what the terminal is doing and the kernel's notion of it... hopefully it won't be hard to fix it, although your work-around of setting UNIXMODE to include "b" seems to work fine. (You don't mention whether this problem occurs under both MiNT and TOS, or just under one or the other... the MiNT libraries leave terminal control up the the kernel if MiNT is running, but have to attempt to emulate ioctl() themselves if MiNT is not present.)

> the global insures that the standard streams are also binary since _main()
> does essentially:
> stdin->_flag = ... | __default_mode__;
> long before it calls your main(). note that the scope of this force to
> binary mode is probably all child processes spawned from the program.

The actual setting of the _flags to binary mode affects only the process involved, since the FILE structure is a library construct, not a kernel one; so binary mode is not inherited by children.

(Of course, changing the UNIXMODE environment variable does affect the children, since the environment *is* inherited unless you do somthing like putenv() to change it.)

Source record: 43819

Hi,

I've typed the HBL / Timer B example assembler program in, and
I just crash the machine when I run it, when it gets to the part
where it executes the VBL_INIT routine in supervisor, via the
XBIOS 38 call...

I just finished moving out of my apartment, and my ST won't be
hooked up to a modem for another day or so... I'll be posting
the program as I have it, in Mark Williams C assembler format.

I don't have the person's name that posted it here, but I've got
it in the comments of the assembler program...

If the person who posted it can check it against the magazine
article, perhaps there's just a simple problem or two...

Post coming soon!

John

Source record: 43815

After experimenting with emacs for a while, I have come up with a number of problems. Using the MiNT version of emacs (recently sent to atari.archive - done by Erling Henanger), it crashes when it does a garbage collection. Otherwise it's great - fast, and supports the 'shell' command.

The other version of emacs (done by Scott Kolodzieski) doesn't crash, but its a lot slower on redraws, and it doesn't seem to support sub-processes (i.e. 'shell')

Has anyone managed to get around the shortcomings of either version? Also has anyone managed to compile the sources for the MiNT version recently send to atari.archive (in atari/new/mntemacs.zoo)

Thanxs Jim

2566. Keyboard interrupt?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-01 16:37:01 UTC
From: mpnolan@vax1.tcd.ie
Message-ID: <1992Jul1.163701.1@vax1.tcd.ie>
Source record: 43816

At the moment, I'm trying to code a text/graphic adventure.
The problem, is that I need to sevice the keyboard.
I can't.

I am using a system call, that samples the keyboard, but
it's a busy wait routine.

I would love to interrcept the keyboard interrupt,
and service it myself, with my own code.

Could someone please show me how to intercept?
-and how to make sense of the hardware regs.?

thanks in advance.

Hi!
I have a problem with a AT-Speed C16-equipped Mega STE/4:
If I try to start up AT-Speed, the emulator screen is built up about 2
times per second, probably by whatsoever-caused frequent resets.
Then I have to restart the ST by pressing <escape>.
I tried to fix it by soldering an additional ground cable from the
AT-Speed-board to the motherboard, but that brought no improvement.
Does anyone know how to repair it? (Please reply by e-mail.)
TIA,
Joe.

2570. Topping windows

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-02 08:45:33 UTC
From: johnj@echo.philips.nl
Message-ID: <1992Jul2.084533.19656@echo.philips.nl>
Source record: 43831

Hi,

Making a GEM application I run into the following situation:

I want to have two windows on the screen at the same time:
A. SCROLL WINDOW (A scrollable text window).
B. BUTTON WINDOW (A window with some self-drawn buttons, usign vdi).

Simplified it should look like one of the following:

```
A. B.
============= ==============
| |^| or | |^|
| ||| | |||
| |v| | |v|
------------- |------------|
============= | |
| -- -- | | -- -- |
------------- --------------
```

Two windows, each one One window completely visible
completely visible, drawn on top of the other
together filling the big one which fills the total
whole screen. screen.

In both situations, all info is completely visible.

I want the user to input on both windows randomly,
without having to top a specific window first.
As this would give a nasty flickering without any use for the user.
It is even worse, as the scrollbar won't be visible if its window
is not topped.

However, GEM assumes that you have only one active window.
Further more, you are not aware if a specific window is not visible
(as early TOS versions do not send the untopped event).

So if a user should click on a button in the button window,
I want to react with an appropriate reaction to the
function of that button, without having to top that window
first (which would lead to flickering, no scrollbar being visible
anymore!!, and no extra information to the user).
A reaction to button click may be an update of its state,
doing internal actions within the program, and changing the
view of the (other) scroll window.

I was thinking of always having the scroll window topped.
Everytime I get a TOP event for the button window, to react
on it as being a possible click on a button (by examining the
x and y positions of the mouse). So I ignore GEM's top request
and will leave the scroll window topped.

Questions:

1. What would be best positioning of windows. A or B?
2. Will this work in all existing GEM versions?
3. If not, what needs to be changed?
4. Any additional remarks?

I do think this will be ok for the current single task system, but...

5. What about MULTI-TOS (or other already existing multi* environment)?

As an alternative, I could do the following (which I do not like to do,
as this will take quite some time to re-implement):
6. If I'd make the buttons real GEM objects, would I get an event from
GEM when the button is pressed, even if they are outside the current
topped window.

Note that I do not want to make a dialog box or a new desk, as the
program should work in multi* environments as well.

Many thanks in advance.

John

I'm afraid its not quite that simple. You'll also need to edit some of the other files, since they in turn call files with long names - eg, try doing an M-x compare-windows on your version. Its worth editing the other files anyway, to get a dumped version of Emacs that suits your needs. For example, I didn't need any of the rmail or ftp, etc stuff, but there where a few things I did want in that weren't included in the basic version.

Incidentally, is there any sign of the updated non-mint Emacs being available yet? The one that, apart from anything else, knows how to launch external programs.

RTFM.
There really is no need to catch the keyboard interupt, from
what you describe.
If you use Bconstat, at various times, it will check for whether a
key was pressed. It's #1,trap 13, in case you don't have docs. Oh yeah,
there's also a devicenum parameter, which would be 2 for the keyboard.

```
Bconstat
move.w #devnm,-(sp) ; #2 for keyboard
move.w #1,-(sp)
trap #13
addq.l #4,sp
```

If you really want to to grab the interupt, it looks like you can use
Mfpint, pushing the vector of the new routine, the register you want to
steal the interupt from on the MFP, and $13, It's a trap #14 call, and
you'd have to check the register mask, I'd assume, to see if bit 6 is set,
(keyboard requestt) and jump top your own routine. Might want to read
CFJ's 13 commandments on vector stealing while you're at it.

```
Mfpint
move.l #pointer to your code,-(sp)
move.l #number of register to change vector for,-(sp)
move.w #13,-(sp)
addq #8,sp
```

BTW, the new 3 part c.s.a.st FAQ arrived on my system yesterday. In it
you'll find a list of sources for all the information you need. Also, the
gemfast library docs are free and have similar info, and the hitchhikers
guide to the bios seems be available for download many places.

When you upload to atari.archive, you should email Jeff with a short message about you program.

It takes ages for anything to be moved from new to the proper place though.

CRAIG GRAHAM.

This is due primarily to the fact that Jeff is no longer AT the University of Michigan. It is a long distance call in order for him to connect with atari.archive. He drives down periodically, and goes through the 'new' stuff.

It's a temporary thing. When he gets to grad school this fall, Jeff should once again have direct, non-long-distance, access. I suspect that's when most folks will be returning from summer vacation anyway ...

> the System is running 16 MHz :-(And Now: The CPU and FPU are new
> and run 50 MHz. The Speed-Up is worst case: 35%.

That's very nice, after such a long time of having my TT I always waited
for some hardwarespeeders. But I heard, this speeder would have a 68030,
and, what I want, is a 68040, especially, when I hear the price of DM
2000 !!

So...I have to wait again...

Maybe, someone creates a nice DSP-Board for the TT and implement it
as in the Falcon030 ? :)

See the source code for isatty() in the MiNT library. This is also the "official" way of telling whether a TOS file handle is connected to a terminal.

For determining *which* terminal a tty is connected to, use ttyname(); this will work only under MiNT, though. (ttyname() works by using MiNT's extended file attributes and directory searching operations; it searches through the u:\dev and u:\pipe directories until it finds a file with the same index number as the handle.)

"xprolog.arc" in the atari/languages directory on atari.archive.umich.edu
is only 54K long. It implements what seemed to me like standard prolog -
I used it for assignments in undergrad.

The problem with adding an '040 is that it drives the bus in a different
manner, so an accelerator board would need to translate the signals.

2583. MiNT: How to suppress access to drives? (2)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-03 10:06:37 UTC
From: itschere@techfak.uni-bielefeld.de
Message-ID: <1992Jul3.100637.9963@unibi.uni-bielefeld.de>
Source record: 43840
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hello world! (2nd try)

This is my second attempt to ask anybody if there is any information on how to prevent MiNT from accessing some GEMDOS drives: The idea is that if you run a multi-user system, you'd probably like some users not to access some data. One problem might be, that the ST can only run one GEM, but what if a remote user calls it too? On Minix partitions you can set the access permissions so that stuff like this will never happen. But there will be the entries in drive U:/ left which can be accessed by anybody. Is there any way to prevent MiNT from recognizing these drives or any other way to make them not occur in drive U: or to make then not accessable by all users? Patching the _DRVBITS system variable works fine, but how should MiNT load the minix partition driver, if its own boot partition c: has dissappeared?

Any ideas? I'll appreciate them!

Well, I've got a better idea, which will work on almost every TOS-Ver-
sion:

make an evnt_multi with the two rects WINDOW1, WINDOW2 as a event, when
the mouse goes in. If this event happens, just top the window, in which
the mouse is, so the user always has only to make one mouseclick.

> I do think this will be ok for the current single task system, but...
>
> 5. What about MULTI-TOS (or other already existing multi* environment)?

Well, that's really a problem. You have to be sure, that both windows
are topped, well sure, only one is active, but the user has to be able
to click in both windows. Then this function will work fine.

Another way is, to merge these two windows to one. Maybe you can make
this... :)

> As an alternative, I could do the following (which I do not like to do,

Well, I know this, but look at the 'old' STs. The 68020 has also got
another businterface than the 68000 and 68010, but there are many many
boards for the ST. And I guess, that the 50 Mhz-hardware is not so much
cheaper than designing a new one for a 68040. (Well, I hope this :)

Greetings, Roland :)

In my opinion, if you show a window attribute, you should handle it.
Otherwise, what is the point? You use precious screen area with those
attributes.

2588. Re: Emacs, MiNT and other goodies

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-03 14:07:54 UTC
From: sundsted@cis.uab.edu
Message-ID: <1992Jul3.140754.13731@cis.uab.edu>
Source record: 43691

As I understand it, in order to use other programs within Emacs (shell, lisp...) you _need_ MiNT. For example, when you type M-x shell, Emacs starts your shell with its input and output taken from Emacs buffer *shell*. While the shell is running, you can still use Emacs. Wihtout MiNT there would be no way of switching back and forth between *shell* and regular Emacs because only one process can be runing at a time.

2589. Mac Hard Drives

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-03 14:27:29 UTC
From: psurge@cs.utexas.edu
Message-ID: <l58ouhINN4sl@levelland.cs.utexas.edu>
Source record: 43693

I saw this thread recently, but did not read it because I didn't think the situation would ever come up. Please bear with me if this is a rehash.

I recently aquired an Everex Macintosh HD. The mechanism is a seagate ST225N set up as SCSI ID 2. It appears to be SCSI imbedded, because the connectors do not look like the same used on my other HD. The cable goes from the HD to two SCSI ports. There is also a smaller connector to the side of the larger one similar to the smaller connector on a non-SCSI drive.

I have an older ICD adapter and an OMPTI controller for the first drive. OMTI (I forget which one it is, ompti or omti) is set as ID 0, drive one is, of course, unit 0.

Now the nitty gritty. How do I patch the Seagate into my system and second, not including defects, will it run?

Thanks, and if you need more information please let me know and I will provide it.

Thanks again

This sounds like a good solution. The Leaf Systems (Associated Press)
electronic darkroom software on the Macintosh has an option to select this
behavior. Because it's different, I found it a little bit confusing, but I
suspect that people who aren't mouse-literate* might prefer it.

(*Most of the people at work find the Mac-type user interface
overwhelmingly complex. We've had to install function-key aliases for 30
or 40 common tasks. Using the mouse isn't as intuitive as many people
assume. It's a skill that has to be learned.)

2592. EMACS 18.58 update!

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-03 17:28:28 UTC
From: skolodzieski@vaxc.stevens-tech.edu
Message-ID: <1992Jul3.122828.1@vaxc.stevens-tech.edu>
Source record: 43695

UPDATED Emacs 18.58,

Sorry for the delay in getting out Emacs 18.58, but I have been tied up with s much stuff that it had to take a back seet for a liitle bit. It is beginning to lighten up a bit for me so I a looking at releasing the new binaries,lisp and ST-TeX documentation next week. The only thing left to do is the documentation, and I am 1/2 way through that. It should make installation/usage/customization much easier.

It does have the ability to directly launch processes. "M-x complile" and "M-x grep" work fine. Screen updates are much faster, and all filenames have been shrunk to comform to the 8.3 TOS limit, the ".emacs" init file has been changed to "emacs.rc" as to be legal under non-UNIXMODE TOS.

Once again sorry for the delay, but I can gaurentee it is worth the wait.

Cheers,
Scott Kolodzieski...

PS. Remember to check out "Bash 1.12" on atari.archive, they are in the files "112src-d4.zoo, 112bin-d4.zoo, and 112doc-d4.zoo" in the atari/new subdirectory.

2593. Gem Questions

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-03 18:40:17 UTC
From: timg@ccwf.cc.utexas.edu
Message-ID: <75171@ut-emx.uucp>
Source record: 43699

Hi,

I am trying to write a GEM shell for Ghostscript and the following questions/problems have arisen:

1) Gem programs compiled with gcc choke when amcgdos is loaded. I know that there was recent discussion of this topic, but I didn't pay much attention, and I don't recall a solution being posted.

2) The Gem shell calls appl_init and opens a virtual workstation. It then Pexecs GS, whose screen driver then makes another appl_init call and opens a virtual workstation. I expected this to cause problems, but it seems to work OK. Is the system behavior well defined in such instances, or will this have unpredictable results on some machines (don't want to change the GS screen driver if I don't have to :-).

3) Is it possible (with or without mint) for a child process (GS) to open a window and write to it, without messing up the window handles or the gem environment of the parent (the shell).

4) I have a dialog box which contains an editable text object, and it does not behave properly. Sometimes when I delete characters, they are not erased from the screen, although the actual string referenced by the object is changed. Also, sometimes lots of vertical bars are typed on the screen instead of the characters I am inputting. Other times, the cursor is not shown in the right place, but will suddenly jump to the beginning after you have deleted all the characters in the string. These problems occur in various mixtures in different circumstances. This seems to be a problem only with what appears on the screen. The contents of the editable string always seems to be correct.

Any information on any of these problems will be greatly appreciated. I am using gcc 1.4 on a 4M 520STf with TOS 1.0.

Thanks,

-Tim Gallivan

Message-ID: <1992Jul3.184553.8403@cs.mcgill.ca>
Source record: 43698

Hmmm. I was sure I typed it in right. I'll check it against what you'll post (I didn't save a copy of what I posted. my fault)

It didn't come from a mag, so I hope I didn't make a mistake that made it crash on anything else but an old 520STfm.

It could just be one single character that I mistyped (as a 1 instead of a 2 in one of those addresses, or something similar.)

Anyways, sorry for the inconvenience. I hope I could get to repairing the error. Unfortunately, I might not be able to get access to internet until september. So don't be angry if I do not reply.

Patrick.

>I already looked in various archives, but I did not find one which seems
>to work on pipes. Yes, I found "less", but I want to have "more". Maybe it is
>in one of those many packages. In any way, I did not find it yet.

i am not 100% certain, but i think less has a more emulation, which may even include not stopping at the bottom of a file (ie exit at end). you can probably map keys for up scroll, etc, out of existence, too. that's what lesskey does.

the other thing to look for is a version of pg(1). note that "less" does not imply lower functionality. less is actually far more capabile than more.
i can also send the diffs to less 177 for making it run under MiNT. i found the recent one posted at atari.archive as having problems in my environment. could this be your problem?

i know i have source for more. i just don't recall if it is PD or not. send me mail after you try the above without success and i'll dig up my source code and see if i can send it...

> gather (from the file itself, since I couldn't make sense out of the
> documentation) the program supports 38400 baud, 72600, and 15600 baud.
> Is this true and will it work?

it will work. the speed will be set at 38,400, but the computer
will lose characters at that speed. i know because I've used the
accessory you're talking about with my USR DS HST modem, which
seemed to report 38,400 as the port speed, but characters would
get lost, and garbage was all over the screen.

if perhaps you have a 16+ mhz ST, you might be able to get it to work.

2597. reading TTL from cartridge port

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-04 00:40:10 UTC
From: reyy@vax5.cit.cornell.edu
Message-ID: <1992Jul3.204010.13440@vax5.cit.cornell.edu>
Source record: 43701

Greetings,

I hope this isn't a silly question, but I want to know how to
interface my ST with an IR decoder via the cartridge port.
My naive approach was to use the power supplied by pins 1 (+5V)
and 39 (GND) to run a radio shack IR decoder module, and send the
output to pin 17 (data 0). Then just read the cartridge port
(address hex FA0000) and presto, I'd have nice raw data.

Well, what really happened was that my ST froze up. Then I would
reboot, and I'd get a whole bunch of bombs. I thought I fried
something internally. But I guess not, because it worked the
next day, so I tried it again, same thing. I really don't know
why it gives me bombs when I try to boot afterwards, but if
I wait a day or two, it's fine.

So, is my procedure as described above OK, or am I missing
something rather significant? Any suggestions as to a better
way of accomplishing this? This is mostly what I'm concerned
with, but if you think you know why my computer keeps crashing,
I'd be interested in knowing that, too!

Thanks,

You can't do that as you must stobe the input to D0, what you are doing in
pulling D0 high or low and crashing the computer..

Also is the output of this device serial..??

- Does anyone have, or heard of a prg for ST that will read .JPGs?

What I've one for a long time is use DJPEG to conver the file back to GIF, and then run DMJ_GIF 3.0 to convert it to spectrum. Works well! If you want it full size, then the GIF_COLOR is a good one... On the TT, my friend uses the latest version of GEM_VIEW to view them with, since he has 256 color that way. GEM VIEW works on teh ST of course, but you only get 16 colors in low res. (That's why I like the conversion to SPC...)

DJEG and DMJ_GIF are both on atari.archive. The new GEM_VIEW might be.

2600. TOS 2.06 Startup Wait Skip

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-04 16:50:13 UTC
From: mario@rbiffm.informatik.uni-frankfurt.de
Message-ID: <3079@rbiffm.informatik.uni-frankfurt.de>
Source record: 43709

I have just installed TOS 2.06 on my old ST1040.

The startup delay to wait for the SCSI-disk to become ready has been done by the hdw3 bootsector, which tweaks the devices at the DMA bus with test-unit-ready commands.

The new TOS introduces a very long delay to wait for disks to become ready. With an additional utility named "NOROACH" the delay may be adjusted or skipped (also a bootsector).

As I am not satisfied with the adjustable wait solution of NOROACH I was planning to modify the hdw3 bootsector to turn off TOS 2.06 initial spin-up wait. Does anybody know what I have do at bootsector run time to change the time of the initial wait?

Perhaps there is a NOROACH source available somewhere?

2601. ST Power Supply Question

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-04 20:48:23 UTC
From: bcc@lanai.Eyring.COM
Message-ID: <1992Jul4.204823.5445@fcom.cc.utah.edu>
Source record: 43705

From previous postings here, I've learned that the ST power supplies leave something to be desired. Well, my 1040 now makes fizzing noises, the LEDs flicker, the screen image on a monochrome monitor is lousy, and the floppy drive won't work. Since the fizzing comes from the power supply, I am laying the blame there.

My options are fix the old supply or buy a new one. If I fix the old one, is it most likely to be a capacitor or the regulator? How can I tell? What is the Radio Shack replacement for the regulator? If I buy a new power supply, does BEST have the corner on the product?

Thanks!

You are causing what is referred to as "bus contention" (that's not important to know, I just love buzz words! :-) This is when two data sources (like your detector and any of the RAM/ROM in the computer) place data on the bus at the same time. What you need is a tri-state buffer that will only allow your detector data to be placed on the bus when the cartridge port address is selected. I've not built a cartridge port interface yet, so I'm not sure of all the bus timing, but I believe you would use the ROM select signal(s) and the data strobe signal(s) to enable the tri-state buffer, gating your data through the device. I have collected some info on the port, but haven't experimented with it yet. Your application of reading one bit from the port will require a little more logic, but not much more. E-mail me for more specific info.

Regards,
Doug Plate

> Please, does anyone know a correct solution? I just want to be able
> to process hardware exceptions in C, and not return from the exception

its kinda hard to do this for the gcc library too in a
portable/general way. the way i have done it in the past is to have
two codings, one for the 68k one for 680X0 (where X >0), and put a test
based on 0x59e:w (which indicates a long frame). the code basically
does what you suggest, that is, hack the mode, and then does a longjmp
to someplace i have done a setjmp already in my C code to handle the
exception. you can see some of this in the atarist-gdb src, and also
in the gmon.c source (in the library). oh, and dont forget to use the
XBRA protocol.

cheers,

> the modifications.

that is correct, because the environment passed by Pexec is the
environment gemdos knew about. on startup, the library make a copy of
the env gemdos knows about, and any putenv()'s happen to the library's
copy and not to gemdos's.

> extern char **environ;
> Pexec(0, ..., environ); doesn't work either.
>

that will not work, you need to pass the env down using the Atari/Mwc
conventions, not just the raw array. (see spawnve.c to see how we do
it).

> like to know why passing environ doesn't work. I have spent quite
> a bit of time messing with this and I am getting a little annoyed.

dont get annoyed, just ask! send mail!

> I am using GCC 1.4 on a 4M 520STF. Help will be greatly appreciated.

what i am curious about is why you are using Pexec() directly, instead
of one of the execXX()/spawnXXX() forms, which are more higher level
and take care of all these issues for you, pass the correct env using
the correct conventions, the spwanvp/execvp() forms even look up PATH
for you, and so on. heck you you even use system() to do redirections etc.

cheers,

I ftp'ed a copy of djpeg and I was just wondering: How much memory does
it require? I have 1 meg and I seem to get out of memory messages on
JPEG files greater than about 20k. Is this normal?

2609. topping windows (continued)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-06 11:56:01 UTC
From: johnj@echo.philips.nl
Message-ID: <1992Jul6.115601.10703@echo.philips.nl>
Source record: 43723

Hi,

Thanks for all reactions.

Although I got some more ideas now, I'm still not convinced about a
particular solution. That's why I react on some topics brought up.
I hope to get the discussion going on.

Summary:
>I want to have two windows on the screen at the same time:
>A. SCROLL WINDOW (A scrollable text window).
>B. BUTTON WINDOW (A window with some self-drawn buttons, usign vdi).
> [wants to handle clicks in both windows without handing 'topped'
> events before]

>I was thinking of always having the scroll window topped.
>Everytime I get a TOP event for the button window, to react
>on it as being a possible click on a button (by examining the
>x and y positions of the mouse). So I ignore GEM's top request
>and will leave the scroll window topped.

In article from reeuwijk@et.tudelft.nl (C. van Reeuwijk) writes:
>1. If you want, you can get a window without move/title bar. Just don't
> specify a move, title, full or close attribute for that window. That
> way both choices are equivalent.
>2. The only problem I see (but I'm no authority on this) is that you don't
> get informed if the right button is pressed, or about double clicks.

I do not know why not. As the multi_event always returns the mouse button
state. This includes the right button. Or do I miss something...

>>5. What about MULTI-TOS (or other already existing multi* environment)?
>
>Someone from atari has stated that your window should at least have a move
>bar.

Question: Is this really necessary, or "just" to allow users to
move the different applications on screen. As I would not like to do that.
I want my application to work with MULTI-TOS. Not necessarily cooperate
with it...

> So much for my advice above. Why don't you allow the user to arrange
>(and perhaps size) the windows?

What about MULTI-TOS? Does it move/clip inner windows (like X and MSWINDOWS)
or is it up to the application programmer (I wouldn't be supprised;-(

In article from rb420@rbhp14.rbg.informatik.th-darmstadt.de (Chris Vetter) writes:

>
>Why should he. I always create windows with all elements (that is except INFO).
>All he has to do is, NOT to handle those elements he doesn't want to be changed
>or clicked or whatever.

If I get you right. You display the closer even when you do not support it
(as an example). I think this would be too confusing for the user.

>|> 2. The only problem I see (but I'm no authority on this) is that you don't
>|> get informed if the right button is pressed, or about double clicks.
>
>You can get information, but as far as I know, this message is in binary.
>I guess it is %0111 for the right button.

Wha? How/where do you get that from?

In article UK1T@DKAUNI2.BITNET writes:

>Well, I've got a better idea, which will work on almost every TOS-Ver-
>sion:
>
>make an evnt_multi with the two rects WINDOW1, WINDOW2 as a event, when
>the mouse goes in. If this event happens, just top the window, in which
>the mouse is, so the user always has only to make one mouseclick.

The problem with this is that the scrollbar will be invisible as soon
as its window is no longer topped...

Currently I am doing something simular. I am using graf_mkstate() and as
soon as the mouse moves out of the work area (Eg. to use the scrollbar)
I am using event_multi again (with a rect to wait for the mouse to come
back in the work area rect.
But this allows no other applications to run when the mouse is in the
work area, so no good for MULTI-TOS (I think).

>> 5. What about MULTI-TOS (or other already existing multi* environment)?
>
>Well, that's really a problem. You have to be sure, that both windows
>are topped, well sure, only one is active, but the user has to be able
>to click in both windows. Then this function will work fine.

This would not be a problem if MULTI-TOS clipped everything outside your main
window or parts that or not topped (because of other applications' windows).
But I have no information about this.

>Another way is, to merge these two windows to one. Maybe you can make
>this... :)

I did think about this. However, I thought it wouldn't be nice,
as the scrollbar is besides the whole window, while the scrollable data
is only in one part of it... You'd expect the buttons to get scrolled
as well (being a user...).

2610. Help! Problem with serial port...

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-06 13:52:39 UTC
From: hack@hector.stsci.edu
Message-ID: <1992Jul6.135239.12716@stsci.edu>
Source record: 43710

Recently lightning took out my modem and the phone my wife was talking on. After replacing both, I am now getting some odd behavior when I run UNITERM. I call up the dialer and have it dial a number. The modem receives the number from the computer (the appropriate lights on the modem flash), I hear it dial the number, the other end responds correctly, then NOTHING.

Normally, the dial command (ATDT########) shows up on the screen, however, it does not any more. When the modem connects with the other end, it usually beeps and then shows the CONNECT 2400 message, but not any more. It appears that my 1040ST RD line has gone south. Does this sound correct? Could anyone provide some suggestions on how/where to check/correct this problem?

[stuff deleted]
>I have seen a
>file (an accessory) that has german documentation. From what I could
>gather (from the file itself, since I couldn't make sense out of the
>documentation) the program supports 38400 baud, 72600, and 15600 baud.
>Is this true and will it work?

Well, I can't say if it will work for your case or not, but I have used the accessory (HSPD_232.ACC) to do null-modeming between my MegaSTe and 286 with no problems at 38400 baud. At least in this case, yes the accessory does work as advertised (it's real cool seeing the files fly at 38400 baud). In case anyone wonders, yes, I know I can put PC disks in my ST, etc. The reason I null-modem is because my PC has a 720k drive, and I'm using 1.44M disks on my ST (now there's a switch, eh? :-)

I do have one "problem" however with this accessory, or rather with its options. The accessory does give the choice of 38400 and two higher speeds, but the speeds that it does have (above 38400) do not match any of the high speeds that my PC term programs handle (namely Procomm and Telix). If there was a way to set a custom baud rate, then that would be even more useful (BTW the PC term supports 57600 and 115200 baud, while the ST supports 38400, 72600 (I think) and 156000 (I think))...

2613. Tex, nroff, ps documentation

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-06 16:39:56 UTC
From: monnier@disuns2.epfl.ch
Message-ID: <1992Jul6.183956@disuns2.epfl.ch>
Source record: 43713

I was just wondering what was the point to distributing documentation
in Tex, nroff or postscript form ?

Is nice presentation so important ?

Personnally, I just want to read it (maybe printed, maybe not) !

-Nroffed manpages could be fine, but I don't know of any package
that can really handle at least half of the manpages found on
MiNT or UNIX.
-For Tex, the problem is just that Tex is big: too big for my HD
and anyway too slow.
-Finally postscript is even worse than Tex to get printed (ghostscript
is also big and slow) !

I LOVE ACSII TEXT !!!!
SO EASY TO HANDLE !!!!

Where could I find a nice util to transfer from PS or Tex to ASCII ?

2615. Which MiNTlibs to use with GCC 2.1??

Newsgroup: comp.sys.atari.st.tech

Hi,

GCC 2.1 with PL20 MiNT libs fails some tests (including bus error on the bcopy test). I assume that this means that there are some errors in Patch Level 20 of the MiNT libraries?

Has anyone had any real programs that didn't work properly because they were compiled under GCC 2.1 and used PL20 MiNTlibs??

(In other words, what I'm really asking is, "Should I fall back to GCC 1.4 and PL19 of MiNT libraries?" Can PL19 be used with GCC 2.1?)

john

So people have the option of producing either plain ASCII, or a nicely formatted (e.g. for laser printed output) manual page.

> -Nroffed manpages could be fine, but I don't know of any package
> that can really handle at least half of the manpages found on

Bill Rosenkranz's nroff handles every single MiNT manual page. It's freeware (thanks, Bill!) and he posted it to comp.{sources,binaries}.atari.st last year.

The only manual page people have reported problems with is the manual page for csh distributed with tcsh. My System V nroff won't handle that either, so evidently the problem is in what the folks from Berkeley wrote, not in Bill's nroff.

Nothing serious. If NetHack works with gcc 2.1 and mntlib pl20 (and it
does :-)) then I expect that most "real" applications will work fine.

PL21 of the libraries will be out someday "soon", depending on how little
sleep I can get by on :-P.

The title says it. Is it possible to upgrade a Mega ST1 or an Mega ST2
by soldering RAM chips into the free positions ?

Or do you need another MMU ? What are the specifications needed if
such thing is possible ?

I'm sorry for my technical ignorance; I know the various cards offered
but I thought it just might be possible.

Thanks,
Thomas.

The reason it works for you is probably that you have a Mega STe,
which can handle the 38400 serial speed. I tried it with my 8 MHz STe
with a Courier HST DS, and there were characters lost and garbage in
everything the modem sent. Probably even the MegaSTe couldn't handle
speeds like 57600 even if the Accessory supported it.

ooh, i get some relief from the zoo/lharc flame fest in .. :-)

>> -Nroffed manpages could be fine, but I don't know of any package
>> that can really handle at least half of the manpages found on
>> MiNT or UNIX.

nroff 1.10p5 usually does a decent job, but there are both bugs and limitations. especially problematic is .TP macros (don't have one) and failure to do .IP correctly (won't put text on the same line as the tag, even if tag is small). .TP's can be converted to .IP's, eg:

```
.TP [optional_indent]
tag
text...
```

becomes:

```
.IP tag [optional_indent]
text...
```

(someday i'll either fix nroff or write something to fix this. also need .ta) tag can have font escapes (eg \fB\-I\fIpath\fR) and n can be specified in chars or "inches". also does not remember indent from IP to IP, but this can be "fixed" in tmac.an with a number reg to remember the indent and reset at the next .PP or whatever. otherwise my nroff should handle all but system-dependent macros (eg convex seems to use .CX for xrefs). it handles .TH,.SH,.PP,.LP,.RS,.RE,.IP,.B,.I,.BR,.IR,.BI,.RB,.RI, and a couple more that i forget now. these represent 95+% of the macros you are likely to find in unix-style documentation anyway. as eric mentioned, extremely complex manpages may cause problems, tho i have not found one yet i can't "coerce" into working. (oh, and i believe tcsh came from cornell)

other options are the cawf port someone did (i have also done this port and cawf works well) and an pending port of GNU groff which i look forward to that someone is doing. cawf is small and suprisingly capable, considering henry spencer originaly wrote in in awk (!). cawf is a C version. groff promises to be exceptionally capable, but both a disk and memory hog (in the true GNU tradition :-).

note that all nroff's will allow the creation of ascii files. you may need a filter (as in nroff -man file | ul -t dumb). the only "advantage" nroff has is there is a standard (ok, a convention) for documentation under unix so everything has a minimum set of information and a common "look". that's about it, really.

you have options...

-bill

I just wanted to thank all of the wonderful people who have contributed so much
to the ATARI user community of which I am a part.

There are many people to be thanked, and most I do not know, but I
just wanted to let people know that they are appreciated and a lot of good
comes from the hard work they put into making and/or porting the software,
libraries, and utilities that I am sure many of us use.

Someday, I would like to be able to show my gratitude by doing my part
in expanding the base of useable and useful material in the spirit of GNU.

My three favorite things are:

Mint094 and Mintlib20 -- better than Unix on an ATARI and in
constant use!

GCC and G++ -- very powerful, very useful!

PD KSH (a Mint Shell) -- does almost everything in the book
as described for the real thing!

P.S.
atari.archive.umich.edu -- who so graciously collect everything
and provide the directorys /mint,
/gnustuff, and so on.

2623. Re: Status of GDB working with G++ ??

> Last I checked, GDB did not work with G++. I have no idead why, but I'd
> like to know so as I can decide whether I can make an input into getting
> it working.

this is correct. the reason is that the atari gdb port is
based on a very old version of gdb, which has been hacked extensively to
bring it upto par with more modern versions of gdb as far as C
language support is concerned, but the C++ support just has'nt gone
in. A brand new port based on something like gdb 4.X would probably
be a good idea, though it will take a lot of work as the structure has
changed considerably, and the monkey shine tricks of the current gdb
port will not carry over (not easily anyways). also, the newer
versions of gdb are based on the more portable (to unix) bfd lib,
which is a non trivial proposition for the atari. what i am trying to
say is that a port based on modern gdb will be much harder than the
one based older gdb, though not impossible. i would like to see it
done this way rather than hack up the present port even more. i
certainly dont have the time in the foreseeable future to do this, so
i will be more than glad if someone steps up for the task.

btw: if you took the apporach that gdb will run under MiNT
exclusively, then the task will be considerably easier with the newer
gdb structure (its harder to fake not having real concurrent processes in the
newer gdb versions). another positive to this approach is that
facilities may be added to MiNT to make this job easier (ptrace(),
supporting the notion of a core files etc).

cheers,

I assume that tcsh has an exec builtin which replaces the shell with some
other program. From the root shell, you can say "exec mgr" and mgr will
become pid 1. Then, when you open your mgr window, enter "exec emacs" and
emacs will be the only process running in that shell window. When you
exit emacs, the window will go away. Under the setup I have described, when
you exit mgr, MiNT will exit, too.

You are right that evnt_multi() always returns the current mouse button
state (although, as I read the docs, this is only guaranteed for mouse
click events). What I meant was that clicking on the right button would not
generate a topped event, although it might generate a mouse button event.
No big deal I guess.

I also found this, the same is true with GCC 1.40 and mntlibs pl20. Have you tried the same executables under TOS? :-) You get a totally different set of errors then! (The most annoying are the stdio and printf errors).

>
>Has anyone had any real programs that didn't work properly because
>they were compiled under GCC 2.1 and used PL20 MiNTlibs??

Yes, I recompiled my port of Rayshade 4.0 using GCC 2.1 (wanting some extra speed) but it produced a flawed executable. The same code worked with GCC 1.40 and mintlibs pl19, and minlibs pl20, so I think there's a problem with GCC 2.1.2. (Flags used for compilation ranged from -O2 -m68020 -m68881 -D_M68881 to no optimisation.. all gave the same results).

Steve

PS. Have you noticed how some programs will double their speed on the TT if you use the -m68020 option on any version of GCC? Maybe Atari should think about doing this with TOS, maybe it would run at a decent speed then.

> as its window is no longer topped...

Maybe do this: make your own scrollbar, (with buttons, etc. like the
other window). Then this will not be invisible, if you top the other
window. But if you do that, you can also put the two windows together
in one, and you put the scrollbar just next to the scrollable items.

> Currently I am doing something simular. I am using graf_mkstate() and as

> I am using event_multi again (with a rect to wait for the mouse to come
> back in the work area rect.
> But this allows no other applications to run when the mouse is in the
> work area, so no good for MULTI-TOS (I think).

Well, hard to say. But if you put the two windows together, make your
own scrollbar, then you can use just evtn_multi(); and everyting, even
MultiTOS has to work fine!

> This would not be a problem if MULTI-TOS clipped everything outside your main
> window or parts that or not topped (because of other applications' windows).
> But I have no information about this.

I guess MultiTOS has to do so. At the CeBit some old programs were
shown, and the windows of these programs where updated, even if the
window wasn't topped. So - MultiTOS does automatical clipping.

> as the scrollbar is besides the whole window, while the scrollable data
> is only in one part of it... You'd expect the buttons to get scrolled
> as well (being a user...).

But also a user thinks first to top a window before using the buttons
inside. Better put the two windows together, it's more Userlike, more
GemLike, etc.

Greetings, Roland.

Does anyone out there know how to solve the problem of the Deskjet printer not always resonding to the Atari ST. It seems like I have to always either reset my ST whenever the Deskjet doesnt respond to a printing command. I recall a few years ago I heard of a similar problem, but cant remember if there was a solution.

Thanks..

2630. GEM, MultiTOS & Windows (Discussion wanted)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-07 14:10:23 UTC
From: itschere@techfak.uni-bielefeld.de
Message-ID: <1992Jul7.141023.16239@unibi.uni-bielefeld.de>
Source record: 43729

Greeting to all intelligent/unintelligent life forms out there!

Concerning all this stuff about MultiTOS and talking about window programming,
I'd like to put the following question:

When using GEM you've got to record every output you make on any window,
because when the time comes that something has happened to it, you (the
program) are responsable for updating the screen. If I'm not running any
vector- or textorientated stuff, I've got to hold a complete copy of what's
in my window, just for the case that I must redraw something. First this is
going to be a unacceptable waste of memory (on ST's with better graphic
features = more screen memory) and second this makes programming more
complicated than it must be.

So how about the idea of a GEM which does this whole stuff of updating and
redrawing windows when topped, itself? Is it so difficult? (Well at least
it would be for me...) Just imagine the advantages! I don't know if the
x-windows here on this sparc statios does so, but I presume it. You can
just forget any WM_REDRAW message because it will no longer be send to
a program. I think this makes GEM programming a lot easier.

Any ideas? Or comments?

>Any ideas? Or comments?

As I see it, there are a few reasons why the responsibility of redrawing falls on the application:

1) You mention that it is a waste of memory to have your program keep track of what to redraw. Actually, though, it would be more of a waste to have GEM do it. GEM could either store all the commands you sent it (and thier associated overhead) or a bitmap. Either of these methods would end up storing more than your program does in most cases. For example, if your program drew a dense full screen grid, GEM would have to keep a list of hundreds of commands or a bitmap the size of the screen, but to redraw it, your program would not have to store anything.

2) In a multitasking environment, there could be activity going on in windows that are partially covered. It is quite easy to just ignore the areas that are covered, then redraw them later when necessary. The alternative of having GEM keep track of what is happening in those covered areas is much harder.

3) Since you _must_ redraw the window when anything else happens (the window is moved, resized, closed, scrolled, etc.), it isn't really any extra pain to redraw it when it is topped.

I agree, this would be nice for the programmer, but it wouldn't necessarily be more efficient. It wouldn't save any memory, since GEM would have to save all the stuff somewhere, and it could take more it GEM decided to save a text screen as graphics.

Also, the x-windows I'm working on DOES NOT back up the widows itself. Whenever I have some graphics plot which needs to be redrawn when I flip widows, it calls the plotting program, which does the whole thing from scratch (slooowwww).

Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I'm posting this for a friend. You can reply to me (I'll forward) or directly to him at bouv@ncc1701.psu.edu.

Posting follows:

Hello Everyone,

First off, I would like to say that I am by no means a regular reader of this newsgroup, so I apologize if this sort of project has been discussed before at length. Also, I would request that responses be emailed, since I don't really have the time to wade through the volume of postings in this group. Thanks!

I have been a long time Atari fan and owner (way back to the 400 days..) and I currently have a 1040STf, with both the SM124 and SC1224 monitors.

Recently I have been considering building a 386 PC compatible system and looking at component prices, it seems that over half my costs would go towards a decent VGA color monitor.

Since the SC1224 is an analog RGB monitor, I have been thinking that it might be possible to use it for VGA. Does anyone out there know if this is possible ?

I would hope it could be as simple as making a new cable and matching the pin outs (with the exception of the audio and some others).

Has anyone out there had any experience with doing this sort of thing?

Thanks for your time.
-Mark

2635. HELP ME - INFO NEEDED

Hey guys,

I hate to clutter the band width with simple stuff but here goes - I'm thinking of switching from my Amiga to an Atari ST for my MIDI needs. Here's where I need some help - do the Atari ST series computers have normal SCSI interfaces, or did Atari install a proprietary format? Also - my Amiga is now running a 68030 processor @ 25 MHz, will I be able to accelerate an Atari 1040ST to this speed? What kind of support does Atari offer to owners? Are there any mags available for users (what are their names).

ANY help getting info about Atari's would be eternally appreciated.

THANKS EVERYONE - Joyce Scott <jmscott@apgea.army.mil>

TOS 2.06/3.06 appears to wait for the 200 hertz system timer (_hz200, 0x4ba)
to reach a value of 18000 (90*200 - 90 seconds).
Simply set this variable to 180000 (but only if it's currently lower!)
when your boot sector is executed - this will completely bypass both the
lengthy memory test and the startup delay.

NOROACH uses the same method.

> ---
>

This is interesting. So far I have been told with absolute certainty
that the software program both works and does not work, and the hardware
modifications both work and do not work.

It was mentioned above that characters were lost. Was that only when the
speed approached the maximum speed, or was that all the time? Did you
have RTS/CTS working and active when you tried it? I noticed dropped
characters and garbage on the screen when I turned off RTS/CTS on my

Supra 2400+ and sent a stream of text at it. Things went fine until the modem started receiving too fast for the computer to handle. Instant garbage...:) This was when I first got the modem. I don't see why the same thing shouldn't happen with faster modems. The principle should be the same?

Does anyone have any comments or help to add? When I get the modem, I'd like to be able to use it to it's full advantage...

> Here's where I need some help - do the Atari ST series computers have normal
> SCSI interfaces, or did Atari install a proprietary format?

The first 3 generations of STs (520/1040STfm, Mega STfm, and 520/1040STe)
had a proprietary HD adaptor, but ICD sells SCSI adaptors. The Mega STe and TT
have SCSI built-in.

> Also - my Amiga is now running a 68030 processor @ 25 MHz, will I be able to
> accelerate an Atari 1040ST to this speed?

Yes, but you will need to buy a Mega STfm, Mega STe, or TT. The Megas can
then have a 68030 board (Dave Small's SST and Turbo (dunno who the company is)
seem to be the best) added in. The TT comes with 32MHz 68030 and a much better
display, and many other fine things...

> What kind of support does Atari offer to owners?
> Are there any mags available for users (what are their names).

To be honest, support is not great. The FAQ list should have a list of
current Atari mags, and several of the professional music magazines have ST-
related articles. However, the MIDI software (and the companies) are generally
excellent at support.

2640. Re: GEM, MultiTOS & Windows (Discussion wanted)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-07 23:30:15 UTC
From: ens@ccu.umanitoba.ca
Message-ID: <1992Jul7.233015.1022@ccu.umanitoba.ca>
Source record: 43740

I already put this in atari.st but I realize it may be better here.

Thanks to everyone that responded after my last query about a GCR on a TT. Most informed me about a hardware modification necessary for the GCR. I got a copy of the document and made the modification but I still get the same behaviour:

I have a new TT with TOS 3.06, and a 1.4M floppy and 10 Mbyte ST RAM. I connected the (modified) GCR and connected a HD containing Spectre 3.0 and a MAC partition to the ACSI port. With or without the Cache on, Spectre gets up to the "Welcome to Macintosh" screen and then freezes. The GCR and HD work fine on a 1040.

Is it relevant that the GCR test fails even though I am not using the floppy drive at this stage?

If anyone has more ideas I would be happy to hear them.

(From my limited knowledge:)

Only the Atari TT has a true SCSI port. The ST (and TT) have a slightly (?) modified SCSI (called ACSI or DMA), but there are interfaces available to convert to SCSI for arount $100 or less (from ICD).

You can allcelerate and ST to 16 MHz, but it's still slowed down by the memory. The TT has a 68030 @ 32 MHz, with the rest of the computer at 16 MHz.

As for support, the best I know of is on this network. Don't look for much from Atari, at least in USA.

2642. MegaSTe 1.44 Drive problems!

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-08 04:32:36 UTC
From: as423@cleveland.Freenet.Edu
Message-ID: <1992Jul8.043236.14188@usenet.ins.cwru.edu>
Source record: 43591

I have a MegaSTe with the 1.44 Drive that is basically
useless. It will not Format correctly, when it does the disk
has bad sectors. I was wondering if this is a common problem
add if there is a 1.44 formatter for the ST? I have heard that
TOS 2.06 will rectify the situation, but I have a disk version
and it will not even give the option to format high density.
Any help is appreciated!

Ken Wallace

I am in the same situation as you, 2.05 and 1.44 drive that will
not format reliable at all. I have now hearda number of possibilities
which I am soon to try out. First is upgrading to 2.06 and see if
that helps, (I am hoping it comes tommorow). Second I have heard that
that the power supply is not good enough. Third I have heard the older ajax
chips may be flakey. I am hoping that with all these things I am trying
out I will get the 'real scoop' on the problem, and will post here on my
results.

From benchmarking the machine (See "yet another useless benchmark" thread in
comp.sys.atari.st) the TT seems to be fully 32MHz, it beats the pants off a
Sun 3/60 which is a full 25MHz 68020 + 68881 machine. The one thing which
makes the machine slow is TOS, it looks like that's been compiled with a
compiler which doesn't optimise for the 68030, this would just about halve
the speed of the code, ie it would run at the same speed as a 16MHz machine.

I'm thinking of upgrading the TOS chips in my ancient 520 STFM (2.5 MB RAM).

The TOS ROM's appear to all be socketed, there are six of them in all (I think I'm looking at the correct chips, they're on the far left of the board).

Is it worth upgrading to TOS 2.05 (or is it 2.06 which is ok to use on an STFM) instead of 1.4?

I don't have a hard drive, as they cost way too much (but if I could find one for 200 quid or less (UK only), I might well consider it).

So where can I buy a six chip ROM set in the UK? How much does it cost?

Thanx.

How much support can the average end-user expect to get from ANY major computer manufacturer? How supportive is Commodore in direct relationship to the hordes of Amiga 500 owners out there?

Naw, I portend that the best support comes from your local user group (if you are lucky enough to be near one), your dealer (ditto again), the GEnie network (more Atari users/developers on this net), and then the Internet (of course).

But support is rather like love... it's where you find it, yes?

And to beef up an earlier reply...
The SST accelerator is available from "Gadgets by Small"
The Turbo 030 and Tiny Turbo accelerators are from "Fast Technologies"
Either one is fast enough to fry your eyeballs! :)

The standard Atari ST needs a SCSI adaptor if you want to use SCSI
devices. It is possible to accelerate the ST with various accelerator
boards, there are many kinds of them.

>your program would not have to store anything.

I agree on this point. In general, there is always some "waste of
memory" associated with a window, because if someting sensible is
to be shown in that window, the corresponding information has to
be somewhere. And the memory needed for this purpose is minimal
if the program takes care of the redrawing because in most cases
the information displayed in the window is known to the program
anyway.
With the program being responsible for redraws, the programmer
still has the freedom to proceed as Torsten suggests. It is
fairly easy redirect the graphics to a bitmap of the size of the
screen and to BITBLT the visible rectangles from there to the
window. Once you've programmed this, you can always plot to your
private bitmaps and forget about the rest, which is pretty much
as if GEM took care of the redraw.
BTW, in the German mag c't, issue 1/91 a method to redirect
graphics to bitmaps of arbitrary sizes is described, along with
an interface for displaying them in a window.
A word of caution: I don't know much about what things will be
like under MultiTOS, but I can imagine that if another process
becomes active while your process has altered the "logbase", all

kinds of weird effects may arise. Of course, this could be
prevented by letting each process have its own logbase, which
would be a sensible thing to do anyway, as logbase manipulations
are possible via clean OS calls.

Some other programming enviroments provide this. The two I have worked with are far easier to write user interfaces with than any environment I have seen for GEM.

They are: VISUAL BASIC for windows.
HYPERCARD for macintosh.

Wish I could use something like these on the ATARI especially VISUAL Basic.
They both have limits, although VISUAL BASIC doesn't have near as many.

Of Course neither Windows or The MAC Toolbox will redraw windows with a regular programming language like C for instance.

Hmmm. As I remember, the 825 was made by Centronics, and all you
need is a parallel printer cable with the right ends on them. I
THINK you will need a cable with DB-25s on both ends, not a
DB-25/Centronics-36 cable.

2659. Curious question

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-09 08:15:00 UTC
From: mpark@milton.u.washington.edu
Message-ID: <1992Jul9.081500.1838@u.washington.edu>
Source record: 43606

Greetings!
The original Megamax C compiler accesses globals as offsets
from A4 (i.e., using the "address register indirect with
displacement" address mode); this limits global storage space
to 32k, but is more efficient in both time and code space than
absolute addressing.
What do more modern compilers do[1]? Do they provide a choice,
or do they force all globals to be addressed as, say, absolutes?
If global references are all absolute, is execution speed degraded
significantly?
Also, to you assembly language programmers: is there a good way
to emulate the old Megamax's segmentation scheme[2] in assembly
(good in that the assembler/linker does most of the work, rather
than the programmer having to hand-code a bunch of EQUs)?
Thanks for any information you can provide.

[1] Some of the more astute readers may deduce that I still use
original Megamax. No comment (Seventh Guarantee rights!)
[2] No "segmented architecture" flames, please.

> *----=< hierarchical systems are for files, not for humans >=-----*

I think the way X goes about this is quite a good way I think..

It is up to the window manager to handle everthing relating to the main screen and the borders of all windows, it is up to the application only to worry about events within thier own window space.

What useually happens when a window is moved is that the window manager moves what was visible of the window, redraws the border then signals the application to rebuild the window's interior. This seems the intelligent thing to do as then the application doesn't need to know anything about the window manager, and doesn't get called if the window was fully displayed before and after the move.

Please! Never use Logbase() in a GEM-based programm. Please use only the
AES and the VDI. Otherwise your program will not run correct on all
graphic boards. Using Xbios() is limited to the standard ST/TT resolutions.

Source record: 43613

Paul, there are at least a couple of options, but I'll describe what most consider to be the best one.

To emulate a Macintosh Plus your friend needs, as a minimum, an ST with 1Mb RAM, double-sided floppy drive, an Atari monochrome monitor and a device known as the Spectre GCR from Gadgets by Small, and a pair of Mac 128K ROMs. A hard drive is highly recommended as is 2Mb or more of RAM.

Setup is a breeze. Plug the Mac ROM chips into the sockets on the GCR cartridge, plug the cartridge into the cartridge port on the ST, and connect the included drive cable to the floppy drive(s). Boot the system, execute the Spectre software included. At the prompt, insert a Macintosh disk with an appropriate version of System/Finder on it, hit return and voila... "Welcome to Macintosh".

You do _not_ need Mac floppy drives as the GCR allows standard Atari ST drives to read and write in Macintosh format. So you end up with a Mac Plus emulator that is up to 30% faster and a larger screen than a _real_ Mac Plus.

No, there is no Mac II emulator available (yet). A new Spectre GCR and legit Mac 128K ROMs could set you back as much as $500 so you need to justify to yourself if it is worth it considering a used Mac Plus won't cost much more.

Source record: 43614

Hi all,

I finally got around to applying patches 1,2 & 3 to MINIX 1.5 - I recompiled the libraries, commands and built a new kernel. When I run "diskrtc icd" I get the following error message:

bmsrtc: ASSERT(idx=9 0>=1 && 0 <=12) fatal

I set "CLOCKS=-DCLOCKS" in the kernel Makefile.

The interesting thing is that if I use my previous kernel with the new commands then "diskrtc icd" works without errors so it appears to be a kernel problem. Is there something else that needs to be set??

>instead of 1.4?

It's probably not a bad idea to go to TOS 2.06. HOWEVER, be sure that you keep your old ROMs and, if possible, get the upgrade which allows you to switch between old/new ROMs, as there are going to be some programs you own which won't work under TOS 2.06.

The July issue of ST FORMAT/ATARI ST USER (I get both, and can't remember which it is...) contains information on upgrading to the new TOS in the U.K.

I'm using a TTM 195 monitor on a TT at the moment, and I think it does an excellent job. Vastly superior to the old Moniterm and TTM 194 units. Extremely good focus across the entire screen, and very good linearity.

ECL is emitter-coupled-logic. What that means is that you're not going to be able to use the vast majority of large-screen monitors on the market, which are analog. VGA's are out.

I definitely wouldn't consider anything less than 19" for the high resolution mode of the TT (1280 x 960). In fact, I'd actually prefer something bigger, around 21". Putting this many pixels on a 19" monitor runs at around 100 dpi, which can be a little rough on the eyes with the small fonts. As it is, the large ST font (8x16) characters on the TTM195 are only 2/3rd the height they are on my 12" SM124 monitor on my ST (which I expanded to fill the screen).

My understanding is that there are a number of good large screen alternative monitors available in Germany, from 19 to 24 inches. I seem to recall names like Maxon and Eico(?). Maybe one of our German colleagues could jump in here with some accurate information?

(By the way, the 19" TTM 195 display actually has only 18" (diagonal) of the tube exposed, and ~16" diagonal of scan area (13.25 x 9.75"). I don't know how other monitors compare, but thought this info might be useful to you. I haven't tried opening the monitor to adjust it.)

2673. Gem program control of mouse and cursor--HOW?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-09 22:10:05 UTC
From: timg@ccwf.cc.utexas.edu
Message-ID: <75568@ut-emx.uucp>
Source record: 43619

I am writing a gem program which I would like to manipulate the mouse
and cursor positions, but there does not appear to be any way within GEM
to do this. Do I have to use the linea stuff, and if so, can anyone get
me started concerning how to do it?

Specifically, here is what I want to do.

1) When a dialog appears on the screen, I want to move the mouse
to an appropriate button, and then return the mouse after the
dialog exits.

2) The GEM program Pexecs ttp programs. Unfortunately, the cursor
is not visible in the ttp programs (like micro-emacs). I can't find
any way to turn it on. Also, I would like to position the cursor at
the top of the screen before Pexecing the ttp program.

For the cursor, I have tried sending the vt52 codes to the screen, but
it seems that these are ignored in a GEM program. Can anyone tell me
how to do these things in a reasonable fashion?

Thanks,

Tim Gallivan

> with the MAXIMUM speed (9600) of the 2400+...

If I did think that, would I have written what I did? :)

I can not think of any other explanation for what happened, since the problem went away immediately after I turned on RTS/CTS. That isn't really important, though, since my original question was whether or not it was possible to make the ST take data at 38,400 baud since I am planning on purchasing a 14.4K modem and the fastest speed the ST can now receive data at is 19.2K. Since the modem compresses text as it receives it, it is fairly likely that the throughput might exceed 19,200 baud (in which case I am losing valuable speed.)

Thanks for your interest, though...

2675. signal() exceptions... esp. in GCC

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-10 05:27:29 UTC
From: warwick@cs.uq.oz.au
Message-ID: <9300@uqcspe.cs.uq.oz.au>
Source record: 43622

I found out last night that:

signal(SIGBUS,MyBusErrorHandler)

does not trap the bus error. It still vectors to the "print bombs on screen" ROM routine.

So I just used BIOS Setexc(...,MyBusErrorHandler). But of course this exception handler runs in supervisor mode.

Basically, I want MyBusErrorHandler() to do something (eg. print message) then exit(1). At the moment I just did this (gross):

```
MyBusErrorHandler()
{
asm("unlk a6; addl #14,sp; movew 0x300,sr");
}
```

Obviously this is VERY POOR, and I believe it will fail on the TT.

Please, does anyone know a correct solution? I just want to be able to process hardware exceptions in C, and not return from the exception to the place the error occurred, but to my own routine (I've though of hacking the supervisor stack to change the exception return address, but that's even uglier, right?

Please don't do this. If you REALLY want to do this, use appl_tplay
and make this an option the user can turn off.

> emulators and/or hardware-based emulators?

The only real _good_ working emulation is Spectre GCR, which reads and formats Mac-Disks as well, as it can handle with a HD. It's almost an Software-Emulation, but some little Hardware is needed to make the normal DD able to read Mac-Disks, also the Apple-Roms have to added as a hardware-part.

There also exist some only-software emulators, but they cannot read mac-disks, and I think, that most of them do not work well enough.

Greetings, Roland.

take this :)

```
void ttp_on(void)
{
v_hide_c(ghandle); /* hide mouse */
printf("\33E\33e"); /* send vt-52 cursor-on */
}

void ttp_off(void)
{
puts("\33f"); /* send vt-52 cursor-off */
v_show_c(ghandle,1); /* mouse on again */
}
```

> For the cursor, I have tried sending the vt52 codes to the screen, but
> it seems that these are ignored in a GEM program. Can anyone tell me
> how to do these things in a reasonable fashion?

If you try to use that in e.g. a window, than you either have to emulate
the cursor by making an inverting rect.-block, or you try to use the
alpha-codes, if there is a cursor included.

Greetings, Roland

SO? What's wrong with Tim's idea? It just helps make the program a little more friendly and faster to use (if done properly). Here's an example from the Sun OpenWindows system... you select Exit (OpenWindows) and a small Alert box pops up in the middle of the screen with 2 buttons. One says, Exit and the other says Cancel. Since this is a potentially destructive option, the mouse cursor is automatically placed over the Cancel button. After the user selects one or the other, the mouse cursor returns to its original position. And on a large screen with lots of real estate, it is appreciated not having to drag the mouse all over creation!

The only caution I would make is not to design a program so as to be a pain for the power user or the user who is quite familiar with it's operation. I hate programs that have no hot key equivalents for common commands and after I finally mouse on the QUIT option I have to wade through two alerts saying, "Are you SURE you want to do this?". All, IMHO, of course! :)

Mega ST1 NO.
Mega ST2 YES
You need 16 1MBit RAM chips 16 condensators and 3 resistor 33ohms
thats all

Greetings, Ewald

2682. Can't link using gcc and gnumake

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-10 19:15:32 UTC
From: mistik@grex.ann-arbor.mi.us
Message-ID: <Br6tHy.HG8@grex.ann-arbor.mi.us>
Source record: 43643
Cross-posted to: gnu.misc.discuss,gnu.gcc.help,comp.sys.atari.st,comp.sys.atari.st.tech,alt.test

Hi GNU netters,

I recently got GNU gcc and gnumake from terminator.cc.umich.edu. The latest version of gnumake (3.62) seems not to work, it always complains about not enough memory, although it has about 3 MB available (I use a Mega ST4). However, I was able to get the previous version (3.60) to work. I use tcsh in unixmode to work with.

When I say I got gnumake 3.60 to work, it is not completely accurate. I don't know where the problem lies, but I wasn't able to make the programs invoke gcc-ld instead of ld. When gas tries to invoke ld, it does not find it, and it stops. All the other compiler programs work but not the linking part of it. I don't think renaming gcc-ld to ld would be the right solution.

Another problem I have found is, that the binary archive for the libraries do not include crt0.o and gcrt0.o, you have to get the sources additionaly to make them.

How should I go about letting the gnu assembler know that the linker is called gcc-ld? (I tried to define LD and LINKER in environment, and in makefile leading to no solution.)

Thanks for any help in advance.

Mustafa Soysal

This needs a small correction: only the TT has a SCSI bus as standard port,
Mega STE does not have a SCSI port or bus. The built in HD is SCSI but you
get a SCSI<->ACSI convertor with it.
The difference is subtle but never the less.

It would be more understandale if you turned off erro correction,
though if the modem expected flow control to work and it didn't who
know what would result. <Maybe the modems using error correction protocals
need to use rts/cts. anyone know?>

That isn't
>really important, though, since my original question was whether or not
>it was possible to make the ST take data at 38,400 baud since I am
>planning on purchasing a 14.4K modem

Michel, despite what it says on the boxes and in the advertising
blurbs, I don't think any of the current crop of 19200 modems ever
even get near 19200 on 90% of the transfers over normal phone lines.
Only under really optimal conditions are the compression functions
going to achieve their claimed compression, and if, like most people,
you mainly transfer compressed binaries, they're useless anyway. MNP5
will actually slow your trnsfer down, and v42 is just smart emough to
know enough to leave it alone if it's already compressed, so it also
uses cycles checking that.
For screen updates on login sessions, usually the updates are
quite reasonable(faster than you can read), so basically trying to go
faster is not really possible, at least in my experience connecting
with many different machine/modem combinations.

Hi y'all!
pate@ra.cs.man.ac.uk wrote on the 08.07.92:
p>The TOS ROM's appear to all be socketed, there are six of them in all (I
p>think I'm looking at the correct chips, they're on the far left of the
I think you're looking at the _wrong_ set of ROMs. TOS 2.06 is the largest
TOS there's been to date and it needs (just) 2 ROMs... :-)
As much as I know in TOS versions <2.05 TOS is in only ONE ROM chip. So
you'll have to buy the TOS Extension Card for 2.06 for the two ROMs...
But, as standart disclaimers apply, perhaps I got it all wrong. :)

p>Is it worth upgrading to TOS 2.05 (or is it 2.06 which is ok to use on an
p>STFM) instead of 1.4?
It is, it is... The guys at AT*RI gave the whole thing a good thought for once
:D and made it reeeeeeally worth the Upgrade. And worhtier even than 1.4...
That's all for now
Aleks A.
As said, standart disclaimers apply.

>
> How come ?
> Is it normal ?
yes, unixmode gives you case sensitivity too. to quote
unixmode.doc (the `c' option):

c -- Pretend case is significant in file names. If this flag is
present, then UNIXMODE programs will not translate the case
of file names in any way, and will assume that case is significant
to the underlying operating system.
The "c" flag should *not* be used in present versions of GEMDOS,
since these are case insensitive. It is provided so that programs
will work correctly under GEMDOS extenders or future versions of
the OS.

> In this case I'm quite unhappy cause it is not so easy to remember
RTFM and be happy :-) :-) !!!!!

> the exact name (as ls shows normal gemdos names).
> Couldn't Unixmode be introduced as another filesystem: this way
> translation would always occur: for ls and all other apps)

certainly. or you can grab yourself a set of utilities that
are UNIXMODE aware (from A.A). similarly, you can grab yourself a
shell like bash or master that are unixmode aware, and they you can
do completions, regexp matches and so on according to unixmode
settings.

> i was wondering if this is more formally documented. i suppose looking
> at the src to ld would help and i will do that eventually. i also have

oh boy! if you had only looked a few one more step further:
in the utilsrc archive you would find <gnu-out.h> that documents
what you are looking for. the stab information is in stab.h/stab.def
also, in the documentation.zoo archive you should find a paper on
a.out, that will help you decipcher some of this stuff.
(oh another confusing point: do NOT bother looking in symseg.h, its
the old gdb stuff that is NOT used any more).

> finally, is the .o format for gcc 2.x identical to that for 1.4 (gas 1.38)?
yes, exactly the same. (the details of the stab contents
changed slightly, at some point, but that does not effect anything,
only effects gdb, and atariST-gdb knows about that change).

cheers,

Replace v_show_c/v_hide_c by graf_mouse (applications should control the mouse with AES functions) and puts by v_enter_cur/v_exit_cur. In addition, going to an 'alpha' mode won't work with windowing environments like Gemini, BGACC and of course MultiTOS. So be careful.

I'm not really sure what you mean. What would make for "optimal
conditions"? A lack of line noise? I have never had problems with line
noise before, so it must be safe to assume that the lines are at least
good enough in that regard. What else makes for better conditions?

Also, shouldn't a true 14,400 modem go at least that fast, so long as
there are no errors? What kind of speeds should I be expecting?

I have been trying to get into basic programming a little and was simply trying to get a program to read filenames from the file selector and output them to a file. In hisoft basic there are commands referring to a "DTA", which accesses info on files and stores date, attributes etc.! I have tried using FNfsfirst% to get files from a directory and supposedly put the info in the DTA, but how do I then access this info!!! The example prog DIR2STR gives only a sub program to get the info, but doesnt tell you where it is :^(Can anyone out there help me...I realize it's not life threatening, but I want to get into programming a little and I just figured this might be a cute little program to write for myself...an exercise you might say :^) Thanks in advance for any help,

I am using a CGA monitor with my atari ST. As far as I know the
SC1224 is similar in design. VGA uses a totally different approach.
Sorry, but it will probably not work.

Actually, a true 14400 will go even faster. ;-) As to speed to
expect, I see actual speeds around 1550-1650 cps, using a USR dual
standard. As to noise on phone lines, you may not have noticed much at
2400, or by voice, but once and a while on my unix dial-up, one of the
older modems doesn't set error correction, and you should see the garbage
spew out.
I don't know what the limitations are, but no one I know has ever
gotten a real 19200 out of any current 14400 on the Atari, so worrying
about hacking up to 38k is silly(IMHO)

My advice is to just install the new serial fix program, (the one
Eric Rosenquist says _really_ works), and a serial buffer expander (works
sort of like a hd cache). Depending on what modem you get, check out the
various setting files people have uploaded to various bbs's, and unless
you're getting rediculously low rates compared to everyone else, don't
worry about it.

I asked a freind to hook his HST up to his TT port that can do >19200,
if he reports a speed improvement, I'll let you know.
Also, many programs use processor dependant loops to calculate speed
when doing transfers. With my Adspeed on, several zmodem programs were
reporting 2000+ cps. Flip the Adspeed off, and down it went.

p.s. Eric R, please e-mail if you read this, my last mail bounced.

I am interested in this as well, although the notion that my machine would
be LOCKED at 38,400 isn't acceptable to me. I often times use my ST
to connect to another machine that runs at a maximum of 9600, so I'd need
to be able to set the system back down.

For what it's worth, I'm using a Supra 14.4 data/FAX modem right now
and it's working out just GREAT. I wondered about it being limited by
the ST operating at a max of 19.2, but often times I'm transferring
compressed data, so I don't think it's being held back TOO much...

2700. Gem program control of mouse and cursor--HOW?

tcue> dialog exits.

Arrrggh.. don't do it.. It is _Most_ disconcerting when the program you are using starts moving the mouse around without you. Most people will feel much more comfortable & even prefer to move the mouse themselves.. (Plus it's good practise for new users!)

Has anyone knowledge of a resident fileselector, that replaces the original TOS one and shows the names, as they are. That means, that it should handle Minix partitions under MiNT.

Or is there a free sourcecode anywhere for a resident fileselector.

2702. 38,400 baud on a TT - possible?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-12 22:13:00 UTC
From: andre@cix.compulink.co.uk
Message-ID: <memo.519425@cix.compulink.co.uk>
Source record: 43646

The subject says it all, really - has anyone managed to get a TT modem port to run *reliably* at 38,400 baud? I know the machine could handle it, but I'm not sure of the best way to modify the software/hardware. Has anyone succeeded? I'm fed up of seeing my download speeds accelerate up to 1920 cps, only to get bottlenecked by a 32MHz 68030 computer!

Thanks,

Andre

2703. problems with GCC cross compiler

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-12 23:13:04 UTC
From: wmagro@uiuc.edu
Message-ID: <BrAttt.Jv9@news.cso.uiuc.edu>
Source record: 43647

I am trying to use GCC on a Sun sparcstation as a cross compiler for the Atari. The compiler works fine (i.e., generates valid assembly for the 68000), but it always calls the sparc assembler and loader, which, of course, give error messages.

I can override the names 'ld' and 'as', of course, but there has to be a cleaner way to tell gcc which ones to use. It seems the collect2 program has something to do with this.

Any help that could be offered is appreciated.

From: wmagro@uiuc.edu
Message-ID: <BrAuAK.K0H@news.cso.uiuc.edu>
Source record: 43648

Hmm, the news system ate my last post...

I have built the GCC cross compiler on a sparcstation, but I am having trouble getting it to use the proper cross-assembler and cross-loader. It always calls 'ld' and 'as' instead of my gnu loader and assembler (for the st).

I can override the assembler and loader by editing gcc.c, but I'd rather not. How can I tell gcc which assembler to use? It looks like the collect2 program is involved...

Any help is appreciated.

>to be able to set the system back down.

Why should you care if your system is LOCKED at 38,400 if your modem can handle it? Remember that the speed of the link from the computer to the modem is irrelevent to the speed at which the modem connects to another modem. You could conceivably have a 76.8k connection to your modem (if it could handle it ie: 19.2k w/.42bis) and still be able to connect to a 9600bd modem. Remember that even if you are transferring info at > 9600, the modems are still transferring info at their base-rate (with compression).

The modems deal with the computer rater >= link rate by caching the data and requesting new data once it has spit out the old data. The great thing about it is you don't have to think about it - the modem does all the finagling neccessary for getting a workable link (you just have to make sure that your link to the modem is correct - RTS/CTS, bps, right cable, etc.).

You shouldn't be (worried). Even with v42bis on, it would recognize that the data is already compressed and still send it off at 14.4k (which if you read above it does anyway). BTW, does anyone know if v42bis compression is better than say ARC? I would presume so (I have yet to see ARC do 4:1 compression) but would it necessarily be able to compress it further or would the ARC compression hamper the compression routines of V42bis? In other words, would it be faster to send unARCed files as opposed to ARCed files (I know it would be futile to do so with .LZH or .ZOO)?

2706. Passing modified environment to child process--HOW?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-13 07:47:26 UTC
From: timg@ccwf.cc.utexas.edu
Message-ID: <75723@ut-emx.uucp>
Source record: 43662

Hi,

Thanks to the people who responded to my earlier questions, and I
hate to be a real pain, especially since this should be easy, but ...

I have tried every reasonable manner of passing an environment which has
been modified by the parent with putenv() to a child process started
with Pexec().

Pexec(0, ..., 0); passes the original environment of the parent, but not
the modifications.

extern char **environ;
Pexec(0, ..., environ); doesn't work either.

I can fill an array with the environment I want and then
Pexec(0, ..., array);, and this works, but this is kludgy, and I would
like to know why passing environ doesn't work. I have spent quite
a bit of time messing with this and I am getting a little annoyed.

I am using GCC 1.4 on a 4M 520STF. Help will be greatly appreciated.

Thanks,

-Tim Gallivan

2709. sozobon and SCM

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-13 08:30:45 UTC
From: monnier@disuns2.epfl.ch
Message-ID: <1992Jul13.103045@disuns2.epfl.ch>
Source record: 43651

I'm porting SCM (a scheme interpreter) to Atari ST !
I already did a 'quick and dirty' port to Pure C, but this time,
I'd like to use MiNT libraries and all those goodies !

I know this SCM is already ported to Atari GNU C, but I haven't this
last one (lack of HD place). I decided to jump to Sozobon C cause
it is freeware, smaller than Pure C and better adapted to MiNT !

Now look at this piece of code:

```
int (varfunc1)();
int (*varfunc2)();

(varfunc1)();
(*varfunc1)();
(*varfunc2)();
(varfunc)();
```

Sozobon accepts every line except the last one. And you know what ?
SCM just uses that last syntax. Of course I could change the declaration
but another problem arises:

```
varfunc1=funtion_hello;
```

is not accepted !
The only solution I found was to translate the calls. Well this problem is
over, but the question remains:
Which is faulty: SCM cause it uses non standart C syntax or Sozobon cause it
doesn't handle all different C syntaxes ?

I have compiled SCM with Pure C and the mint library. The next version of SCM
will contain the project file.

Due to the ill signal handling in the original Pure C library, Pure C cannot
compile SCM without the mint lib.

>Which is faulty: SCM cause it uses non standart C syntax or Sozobon cause it
>doesn't handle all different C syntaxes ?

SCM uses standard C syntax (only what it does to the stack is not really
ANSI standard ;-). It is Sozobon than doesn't handle standard C.

BTW: the GCC compiled scm is faster than the Pure C version (and only about 20k
larger).

From: basil@eniac.seas.upenn.edu
Message-ID: <82920@netnews.upenn.edu>
Source record: 43659

Hello! Well, I am currently stuck with the infamous Laser C with all its annoying bugs and ridiculously bad Resource editor. I'd be happy to try Sozobon or GCC if I knew what the best resource editor out there is -- ie.

are there any RCS that are nice enough to allow you to simply load graphics /icon files for creating icons, or do you have to edit them all from scratch?

Are there any that, like on other platforms, actually write the C code for you after you describe how you want the interactions?

Are there any that allow you to easily customize things like buttons (make 'em round) for creation of nifty interfaces (much like Neodesk, and Cubase have)?

Also, I have heard good things about Pure C, and know it is being released here by Gribnif (who make a nice icon editor -- wish they'd expand it for making resources). But, will the docs still be in German?

you want patch, tho i supposed ed(1) would work, too, provided you made "diff -e" diffs. patch typically works with context diffs ("diff -c").

there is a version of patch on atari.archive (~/atari/gnustuff/tos/patch is the dir). also posted to comp.sources.unix (check archives). patch is another fine larry wall production. very portable...

2720. Accelerating the 68000

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-13 20:15:45 UTC
From: krakover@spot.Colorado.EDU
Message-ID: <1992Jul13.201545.16477@ucsu.Colorado.EDU>
Source record: 43663

I have a 1040ST and my friend has a Mac+, they both use the 68000. We
were thinking of speeding up our machines. We both know that there are
accelerators that just plug onto the motherboard, but after some discussion we
believe it can be done much-much easier and cheaper.
The first point, the 68000-8, this chip was designed to work at 8 MHz
and either could be replaced with a 68000-16 for around $40? or probably could
be used as is. I used to work as computer support and a common way that a
manufacture could lower its price was to use 8MHz chips at a 16MHz speed, some
work, some wont.
The second point, the memory managment unit(MMN) works at 150 ns,
that's about 6.6MHz, this too, along with the memory chips would have to be
replaced or speed up.
Also, you'd probably want to reburn your ROM's onto faster EPROMS
since there only working at about 4MHz

Is there anything else to consider?

Thanks,
Jonathan

There is a file somewhere in netland describing how to this. There was
a textfile and a picture showing how to speed things up. You just had
to take the 16MHz clock from somewhere and a couple of 74HS gates to
perform the trick. It included a switch for 8/16 MHz.

Unfortunatley I can't remember what the file was called, just something with
16 in it. Send me an e-mail and I'll see what I can do.

I don't suppose you'd be prepared to let us all know the secret to getting the faster baud rates working on a TT, would you? I use a variety of comms packages (including some dedicated/specialist stuff), so unfortunately your entire program (excellent though I'm sure it is) wouldn't really help me.

Perhaps you might like to consider releasing a small AUTO program with a CPX control panel? I for one would find it *very* useful.

Thanks,

Andre

David: Could you post a note on upgrading TOS to 2.06, with the
switchable upgrade. (I don't have access to ST FORMAT/ATARI ST USER)
Will this work with Mega STs produced for the USA?

last year I upgrade to TOS 1.4 using the 2 CHIP set, and last
night I finally gave up and replaced the set with the original
(I think it is 1.2?).Now I can use most of my older programs,
(Games mostly, although WP also runs better on the older TOS)

This may be available via ftp , but I'm on a closed system that will not
allow me use ftp outside of my company.

thx,

fred

<stuff delete>

Yeah, I know. What I failed to get across is that my 9600 connection to
another computer is done via null modem. I NEED to be able to set my
cpu down to 9600, so I'm not willing to lock my system at 38400 (
although I'd sure like to see it once!)

Got any idea where I can find the HSPD_232.ACC file I keep reading
about around here?

If you do the crystal change, you won't be locked in at 38,400baud, but you *will* need to patch your XBIOS Rsconf routine to set the right delay values for each speed, and to allow you to select faster speeds than 19200. Then as long as all your telecom software uses the standard Rsconf values to set the serial port speed, as opposed to messing with the MFP timer directly, you'll be OK. There's really no good reason for a program to be tweaking the timer itself, unless the program is trying to use the timer for a purpose other than a baud rate generator, which is really reaching...

Hm. I think I missed something, it occurs to me that to get 38400 baud thru the MFP, you need a crystal twice as fast as the current one. The current one is 2.4576MHz, and doubling that would exceed the MFP's maximum clock speed of 4 MHz. That's assuming you stick to playing by the rules and using async mode. If you get rid of that internal divide-by-16 you get a much wider range of possible speeds, but it's never seemed too reliable to me.

>appreciated not having to drag the mouse all over creation!

Personally I hate programs that do things like that. The example you
give is a good one: I ask Sunview to stop, and it displays a dialog
box. Since I know without looking where my mouse pointer is I immediately
start moving the mouse to go to the Confirm button. But wait! The darned
program was trying to be clever and moved it for me! AAARRRGG.

To put it more theoretically: by warping the mouse pointer you disrupt
the feedback loop of mouse positioning action of the user, and you weaken
the illusion that the mouse pointer is connected to the mouse.

Or to put it yet another way: don't try to be clever in a program,
try to be predictable.

To handle a large screen area, you could use a mouse accelarator: if
the mouse is moving fast, move the mouse pointer even faster. If done with
moderation, the feedback loop won't be disrupted, since the user does not
have an accurate 'feel' for speed anyway, and will slow down the mouse
movement for accurate positioning. Ofcourse, the mouse acceleration should
be a system feature, not a program feature to ensure predicatability.

The only (and in this case, MAJOR) drawback of this way of accelerating
your Atari is that you won't get a very drastic speed-improvement. The
overall speed-increase isn't more than maybe 10-30 percent depending
on what type of program you're running. I don't think the trouble of
desoldering the 68000 is worth such a small speed-improvement. However,
if you're a hardware-freak you probably already have had your 68000
desoldered and put in a socket. If that's the case then this modification
really is something for you! :-)

It works by feeding the new 68000-16 with a clocksignal that depends
on the status of the bus. If the processor is reading/writing data
from/to the bus then the small logical circuit will feed the processor
with 8 MHz. If the bus is inactive the processor will be fed a 16 MHz
signal. Unless your program only consists of instructions that cause
very little bus-activity you won't notice any major differance. There
are of course programs that will gain quite some speed from this small
(and apart from the desolering, easy modification). Since I haven't
tried this modification myself (I've got a MSTE now :-) I can't give
any real examples, but my guess is that programs with heavy calculations
(such as CAD and DTP-programs) will gain some welcomed speed.

I _think_ you can compare this modifications speed with that of a MSTE
running at 16 MHz with the cache turned OFF.

Source record: 43677
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Well, I dragged out my hacked up Zmodem to play with again between my Mega ST and my STe. I also had the HS_FIX program installed, with a patch I made to have the receive and transmit routines set the IPL mask all the way up. (As it turns out, this probably did nothing at all, since the RS232 interrupts are just about the highest level in the system already...) What I observed this time around was this: Set at 38400 baud, I got one or two garbage characters every 3 and a half seconds (thereabouts), like clockwork. WHen I dropped down to 19200, using the same high-speed mode, I got a garbage character every 7 or so seconds. Sensing a pattern, I stepped down to 9600, and counted up to 13 before I saw garbage. When last I posted on this topic many months ago, I chalked it up to some other clock interrupt and went on to other things. Now I'm not so sure; it's certainly very regular but it really doesn't seem to be related to any of the system timer interrupts. I thought perhaps it was related to the RS232 buffer size, maybe the overhead of wrapping around inside the circular buffer was killing it, but Zmodem uses a 16K RS232 buffer so that can't be the cause. Who knows, maybe it's a function of the number of bits or bytes sent, and I just noticed a particular time because my key-repeat rate worked out to that value. I guess I need to experiment a little more...

Anyway, the fact that it works at all convinces me that it should work all the time; the fact that it screws up once every N-sized-intervals tells me that something fixable is in the way, but who really knows, eh?

Can anyone tell me the format of *.CVG files (Calamus vectorgraphics),
or perhaps of *.CVD (Calamus vectordocument)? I would like to read
and write this file format from my own program, but deciphering the
format by hand is very cumbersome.

Given their protective attitude towards the *.CFN (Calamus font) format,
I assume this information cannot be obtained from the authors, but a number
of commercial programs import and export it, so it *is* possible
to decipher it.

If I get any reliable information, I will summarize it on the net.

Thank you in advance.

From: don@cc.gatech.edu
Message-ID: <1992Jul14.175306.4532@cc.gatech.edu>
Source record: 43681

I recently turned on my hard drive (an 80Meg Seagate and a Syquest 44Meg in an E. Arthur Brown enclosure & power supply, with an ICD controller) and it started to spin up, then died. Turned out the line fuse was blown. Further troubleshooting (and several fuses later) I determined that the problem was the power supply. Even though the AC lines don't show a short on the ohmmeter, it instantly blows the fuse when power is applied. I called EABCO and they no longer stock the case and supply.

Two questions:

Any idea what the problem might be? Any idea of where to start looking? I'm not afraid of a soldering iron, but my electronics training came from the USAF when tubes were still considered hi tech! :-)

Assuming I can't find a problem and get tired of wasting fuses, can someone suggest a source for a replacement supply? From stuff written on it, it appears to be a 60W supply. It has connectors for three drives, and sits in the rear of the shoebox. I suppose I could just buy a new enclosure with power supply but having recently left a real job to become a student again, I'd like to keep the cost down.

Thanks for any advice you can give me!

Source record: 43546

I'm currently knee deep in a pretty big project that up to now has been divided into two phases, each developed with a different C compiler. The trouble is: now that it's time to mesh them together, I need one compiler that can do all the tricks of both, and neither of them fit the bill. What I want to know is, does it exist? (I'm using Turbo C and the old Sozobon right now...)

Absolutely needed:
16 character object names (TC)
Big (Neil Forsyth's "big") libraries (Modified Sozobon)
Works with libraries produced with Sozobon (Sozobon)
Works in 1 meg (Yeah, yeah, I know...) (TC & Sozobon)

Would be nice:
ANSI prototyping (TC)
32 character object names (TC)

From what I understand GNU is out 'cause of the one meg limitation. Does either Sozobon 2.0 or Heat & Serve handle all this? How about Pure C?

This statement caught my eye, and frankly I am somewhat confused. Just what is the "rest of the computer" that you expect should go faster than (or equal to) 16MHz? The TT (or rather the '030) uses an asynchronous bus - it uses data as fast as it can get/take it. Your UART has a set maximum speed, and thus your clock to it is maxed at a finite speed - I think the UARTs in the TT do use a 16MHz clock, but so what if it uses 16MHz to achieve 19.2kbps or whether it uses a different divider and uses a 32MHz signal -> you still get 19.2kbps. Same with the floppy controller (although, since they are supposed to be able to handle (eventually) the 2.88MB floppies, they must have a feed to a 32MHz signal, contradicting your assertion). Sound? The sound subsystems take sound info as fast it can get it from memory - if you put in 30ns memory, you could feed sound to your DMA regs in 32MHz bursts (but who'd want to pay big $$$for the megabytes of 30ns memory, and who needs 32MHz bursts to two (four) sound channels that max out at (this may be wrong - don't have the docs) 23kHz anyway? Video? Goes fast enough to do the refreshes necessary for the VGA monitor, what would extra speed get you? Granted, for big-screen displays, the video update is a little slower, but that can be attributed to several reasons: the one-wait-state imposed by using the VME bus, memory speed limitations, slow/inefficient video circuitry, slow/inefficient video drivers, etc.

In fact, with the exception of the new Local Bus (tm) PCs, what PCs on the market with clock rates above 16MHz actually have subsytems that use a bandwidth above 16MHz (as the assertion that the "rest of the TT runs at 16MHz" would imply that something else does not have this limit)?

If this comes out sounding like a flame at Paul, it was not intended as such. It just that trying to rate an asynchronous bus by MHz seems rather useless. I should think that it would be possible to hook two devices up to an asychronous bus that actually run faster than the CPU, but what good would that be? Actually, now that I think about it, I suppose you could have two processors running at say 32MHz and have all accesses from the two CPUs multiplexed/interleaved (not sure of the correct jargon) on alternate clock signals so they have no bus contention (of course you would have to have an extremely sophisticated bus that would be able to arbitrate the activities of the CPUs simultaneously since most (some?) CPU cycles span more than one clock cycle). But it _could_ be done, and you would have a _technically_ 64MHz bus with 32MHz CPUs, it just would be impractical.

2743. MOD file format wanted

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-14 21:59:32 UTC
From: fdomingu@cerberus.UWaterloo.ca
Message-ID: <BrEFr9.7E1@watserv1.waterloo.edu>
Source record: 43686

Seeing as there's decoding information for various picture formats, I'm curious as to where I can find source or documentation on how .mod files are decoded and how as in the Atari are they used. I know of TCB sound trackers and various players but would like source code to or a description of the format.

Hi,

The ST line of computers uses a 8MHz clock so you don't really need anything faster than 120ns chips. Of course if you can't get 120ns chips, then the faster ones will work fine (and can then be used if you wish to move the memory to a faster machine...:).

-Mike

<deleted stuff>

Perhaps I was overstepping my technical limits when I said this. I was simply repeating what I had read many times on various news articles talking about the TT's speed. I think you clearly know more about the subject than I do, and I appreciate the clearer information.

Personally, I think my TT is plenty fast enough, without debating all these various internal speeds (but then, I had been using an Atari 800XL for eight years).

2746. Identify CPU or clock-rate from within software (HELP NEEDED)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-14 23:25:43 UTC
From: wjr@pacific.uucp
Message-ID: <1992Jul14.232543.11572@jato.jpl.nasa.gov>
Source record: 43689

Is there any _reliable_ way to determin what CPU is on a computer from a within a program (C or asm) (i.e. is this a 68000, 68020 or 68030). OR, perhaps a simple test for determining the clock-rate. This would be for automatically adjusting a programs parameters to fit the speed of each CPU.

>description of the format.

Here's the file format... No source, sorry.

Protracker 1.1B Song/Module Format:

Offset Bytes Description
------ ----- -----------
0 20 Songname. Remember to put trailing null bytes at the end...

Information for sample 1-31:

Offset Bytes Description
------ ----- -----------
20 22 Samplename for sample 1. Pad with null bytes.
42 2 Samplelength for sample 1. Stored as number of words.
Multiply by two to get real sample length in bytes.
44 1 Lower four bits are the finetune value, stored as a signed
four bit number. The upper four bits are not used, and
should be set to zero.
Value: Finetune:
0 0
1 +1
2 +2
3 +3
4 +4
5 +5
6 +6
7 +7
8 -8
9 -7
A -6
B -5
C -4
D -3
E -2
F -1

45 1 Volume for sample 1. Range is $00-$40, or 0-64 decimal.
46 2 Repeat point for sample 1. Stored as number of words offset
from start of sample. Multiply by two to get offset in bytes.

48 2 Repeat Length for sample 1. Stored as number of words in
loop. Multiply by two to get replen in bytes.

Information for the next 30 samples starts here. It's just like the info for
sample 1.

Offset Bytes Description
------ ----- -----------
50 30 Sample 2...
80 30 Sample 3...
.
.
.
890 30 Sample 30...
920 30 Sample 31...

Offset Bytes Description
------ ----- -----------
950 1 Songlength. Range is 1-128.
951 1 Well... this little byte here is set to 127, so that old
trackers will search through all patterns when loading.
Noisetracker uses this byte for restart, but we don't.
952 128 Song positions 0-127. Each hold a number from 0-63 that
tells the tracker what pattern to play at that position.
1080 4 The four letters "M.K." - This is something Mahoney & Kaktus
inserted when they increased the number of samples from
15 to 31. If it's not there, the module/song uses 15 samples
or the text has been removed to make the module harder to
rip. Startrekker puts "FLT4" or "FLT8" there instead.

Offset Bytes Description
------ ----- -----------
1084 1024 Data for pattern 00.
.
.
.
xxxx Number of patterns stored is equal to the highest patternnumber
in the song position table (at offset 952-1079).

Each note is stored as 4 bytes, and all four notes at each position in
the pattern are stored after each other.

00 - chan1 chan2 chan3 chan4
01 - chan1 chan2 chan3 chan4
02 - chan1 chan2 chan3 chan4
etc.

Info for each note:

_____byte 1_____ byte2_ _____byte 3_____ byte4_
/ \ / \ / \ / \
0000 0000-00000000 0000 0000-00000000

Upper four 12 bits for Lower four Effect command.
bits of sam- note period. bits of sam-
ple number. ple number.

Periodtable for Tuning 0, Normal
C-1 to B-1 : 856,808,762,720,678,640,604,570,538,508,480,453
C-2 to B-2 : 428,404,381,360,339,320,302,285,269,254,240,226
C-3 to B-3 : 214,202,190,180,170,160,151,143,135,127,120,113

To determine what note to show,t the source code for the cruncher/decruncher from us if you need it,
but I don't understand it; I've just ripped it from another tracker...

In a module, all the samples are stored right after the patterndata.
To determine where a sample starts and stops, you use the sampleinfo
structures in the beginning of the file (from offset 20). Take a look
at the mt_init routine in the playroutine, and you'll see just how it
is done.

< captured from ModEdit 2.00 documentation >

Editing the effect field

The effect field consists of 2 parts: a command and an
argument.

The command can one of 16 values: 0 1 2 3 4 5 6 7 8 9 A B C
D E F. These commands control various aspects of note and
song playback. An effect command generally takes effect
starting immediately with the note field associated with that
effect.

The argument is one byte long and is represented in
hexadecimal. A hexadecimal byte, in case you don't know, is
a base 16 representation of a number that consists of an
"upper nybble" and a "lower nybble", each of which may take
on a value of 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, A, B, C, D, E,
or F. Values from A - F correspond to the decimal values 10
- 15.

Certain commands listed below use the 2 nybbles separately
(e.g. arpeggiation). In this case, the 1st nybble is one
argument, and the 2nd nybble is the 2nd argument. Other
commands treat the 2 nybbles jointly as one byte (e.g.
speed). In this case, the decimal equivalent of the
hexidecimal number is calculated by: (upper nybble * 16) +
lower nybble. So, for instance, an effect of "F 1D" would
mean set the song speed ("F") to 29 (1*16 + D = 1*16 + 13 =
29).

Here's a list of effects and their required argument byte.
"xy" for the argument byte means each nybble is treated
separately; "xx" means they are treated jointly as one byte.

0 -- AREPEGGIATION
Format: 0 xy

Plays its associated note in arpeggiated fashion; that is, it rapidly steps the note between 3 pitch values: the original pitch value, the original pitch value + "x" number of halfsteps, and the original pitch value + "y" number of halfsteps.

1 -- SLIDE UP
Format: 1 xx

Slides pitch up; slide speed is determined by the xx argument (remember, it's in hexadecimal).

2 -- SLIDE DOWN
Format: 2 xx

Just like SLIDE UP except it slides the pitch down.

3 -- SLIDE TO NOTE
Format: 3 xx

Similar to slide except it slides the pitch TOWARDS the pitch of the associated note field (commands 1 and 2 only specify a speed, not a destination). xx is the speed to slide the pitch.

wn. If x is specified and y
is 0, the volume is slid up at speed x. If y is specified and x is 0, the volume is slid down at speed y.

B -- POSITION JUMP
Format: B xx

Breaks the pattern (i.e. stops playing it at its current position) and jumps to position xx (hexadecimal!) in the pattern sequence table.

C -- SET VOLUME
Format: C xx

Sets the volume for its associated note unit to xx. Note that it only takes effect with its associated note unit, not subsequent notes. Valid volume range is 00 - 40 (hex).

D -- PATTERN BREAK
Format: D 00

Breaks the pattern (i.e. stops playing it at its current position) and goes on to the next one in the pattern sequence table. The argument is meaningless.

F -- SET SPEED
Format: F xx

Sets the speed of the song; hex values 00 - 1F are valid.

2748. Mega ST Bombs Often ?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-15 00:37:43 UTC
From: freds@hpcc01.corp.hp.com
Message-ID: <1550010@hpcc01.corp.hp.com>
Source record: 43548

Have you seen this problem before???

My Mega ST2 is bombing more and more often these days.

usually 4 bombs, sometimes, it just starts writing
what appears to be hex code to the screen before bombing.

This begins to happen as I use the machine for a 1/2 hour or
more, with about 90 minutes being the max time.

Mostly heavy graphics, or sounds games cause the bombing
or even the trusty old WP 4.1.

I did not have the problem when I first bought the system.

I'm one of the original Mega ST purchasers (sp?). I traded
a 1040 for the Mega when the Mega was introduced.

I thought the problem was the TOS 1.4 upgrade that I put in about
a year ago. So a few night back I put the original back.

Well it worked fine for awhile then the same symptoms returned.

Could it be the famous Atari Power Supply. I saw a replacement
from Best Electronics.

Thanks for any and all help.

On the ST, use the _CPU cookie. If there's no cookie, you're on a 68000;
otherwise, the cookie value is either 0, 20, or 30 for the 68000,
68020, or 68030 respectively.

> OR perhaps a simple test for determining the clock-rate. This would be for

It's far, FAR better to use the various clocks in the system to do this.
Relying on CPU timing is a very dicey operation, and is exactly the sort
of thing that breaks every time a new computer comes out :-(.

2752. Midi from the serial port?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-15 02:58:41 UTC
From: jmw@lad.med.utas.edu.au
Message-ID: <jmw.711169121@lad>
Source record: 43544

Just wondering while there's so much discussion aboutf tweaking the serial port to get more into and out of it, how does one go about deriving Midi from the serial port. I think there are some commercially available devices which will do this, but I've never sighted one. Maybe there's a general design for a serial <-> MIDI interface. Any ideas (if there such a design) on how to make it go with the ST[f|fm|e].

Thanks,

You can use any Multisync Mono Monitor such as an NEC Multisync GS.

The ATARI SM 147 is just such a monitor, but it is a lousy one. The big disadvantage to this are a: you must wire an adaptor to plug into the ST. Use the cable from tour SM 124 for parts. Of couse the cable is supplied with the SM 147,

The really big disadvantage is -- No Speaker -- Even on the Atari monitor , you'll have to jury rig one.

Hello word,

Shurely somebody will be able to help me :

I am trying to establish a connection between my camescope (sony
camera) and my STE 512 with RS232.

The protocole for the camera is asynchronous 9600 bauds.

There is a multiplexed line and the systems have to exchange a 8 words
frame.

I can read the informations without any problem.

But I can't write (to send orders) when I want (in the 2 first words of
the frame) :

It begins to work, but if I move the mouse since I am sending, the
words are not sent in the exact time and the camera don't understand.

I think that the interruptions are involved :

(I work in GFA basic and I call an assembly routine to synchronise and
send the informations)

To desable interruptions I have tryed :

- supervisor mode (on)
- write 0 in &H452 (desable VBL int)
- set bit 10 of sr (status register) to desable system int (I hope)
- use XBIOS(26,6) to desable MFP interruption nb 6 (keybord midi
joystick)

- use XBIOS(27,6) to validate MFP interruption nb 6 (keybord midi
joystick)
- clr bit 10 of sr (status register)
- write 1 in &H452 (validate VBL int)
I can read the informations without any problem.

But I can't write (to send orders) when I want (in the 2 first words of
the frame) :

It begins to work, but if I move the mouse since I am sending, the
words are not sent in the exact time and the camera don't understand.

I think that the interruptions are involved :
ved :

(I work in GFA basic and I call an assembly routine to synchronise and send the informations)

To desable interruptions I have tryed :

- supervisor mode (on)
- write 0 in &H452 (desable VBL int)
- set bit 10 of sr (status register) to desable system int (I hope)
- use XBIOS(26,6) to desable MFP interruption nb 6 (keybord midi joystick)

- use XBIOS(27,6) to validate MFP interruption nb 6 (keybord midi joystick)
- clr bit 10 of sr (status register)
- write 1 in &H452 (validate VBL int)
- supervisor mode (off)

Playing with XBIOS(26,6) is OK if I don't move the mouse but I loose the control if I move it. (The job was to allow moving of the mouse since the system is sending...)

Any idea ?

I am not even completely shure to be on the right way for my problem...

Any help will be greatly appreciate,
Thanks per advance,

2757. Re: Passing modified environment to child process--HOW?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-15 10:31:01 UTC
From: jensk@hpbbrd.bbn.hp.com
Message-ID: <9130020@hpbbrd.bbn.hp.com>
Source record: 43568

Bear in mind that `environ' points to an *array* of char pointers, whereas Pexec() wants to see a *single* pointer to a *string* containing all environment entries, concatenated.

Example (NUL chars made explicit):

environ --> ptr1 --> "FOO=BAR\0"
ptr2 --> "ARRGH=GULP\0"
ptr3 --> NULL

Pexec env --> "FOO=\0BAR\0ARRGH=\0GULP\0\0"

You'll *never* be able to pass `environ' to Pexec() - use the exec...() library functions.

Hello everybody!

My Mega ST is dead.
I think I've found the problem, but don't know the best way to
repair it. The problem is the small board on the 68000. I know
that it contents a D-flip-flop to protect the system against
errors coming from the bitblit-chip. The problem is, that it
seems to cause (at moment) a low-pegel at 1.6 V, which means a
reset.

My question now, how important is that board at all and
what is the fastest and easiest way to repair it. (Beside exchanging
the 74LS74 on it)

I hope someone knows a nice trick :)
Many thanks in advance for every answer!

2760. TT Fast RAM

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-15 14:49:09 UTC
From: dud@hardy.u.washington.edu
Message-ID: <1992Jul15.144909.10269@u.washington.edu>
Source record: 43556

I am possibly thinking of either getting an '030 accelerator board for my Mega STe or selling the Mega STe to get a TT. I need an '030. I have heard several things about the 32 bit ram... is it true that fast RAM is the same as ST ram, except just arranged so it can be accessed 32 bits at a time? If this is true, why do people pay so much more for fast ram?

If I get a 2-meg TT, can I just plug 8 megs in it, 4 of them being fast RAM, or is a board required for more than 4 megs? Basically, what is my cheapest option as far as RAM goes?

[...]
The biggest part of the "rest of the computer" would have to refer to memory
access. Now, I'm speaking in a hypothetical sense, because I do not know the
architecture of the TT. Basically, we're talking about wait-states.

On most modern processors, when the CPU has to read/write it's system dynamic
RAM, it has to stop and wait an extra cycle or two because the RAM is much
slower than the CPU. The fastest affordable dynamic RAM's are at about 70nsec
right now, so if you were actually able to run them at top speed, the
effective bus speed would be about 14Mhz. Whenever the CPU needs to access
this RAM, it must slow down, slowing down whatever task is taking place.
Since the clock cycle marks a discrete chunk of time, a CPU wait state would
be at minimum, half a clock cycle and typically more, reducing the effective
bus speed.

This is where cache comes in (but that's a whole nuther story)!

Also, keep in mind that the external clock freq. of a CPU is a deceiving
measure CPU speed since the CPU will divide it internally by two, four, etc.

> RCS...are there any that let you customize buttons, like create round
> buttons

GemFast v1.8 (now in beta testing) has support for rounded radio buttons,
and also for CUA-style buttons (checkboxes and such). It'll be released
pretty soon, both bundled with HSC v1.40, and as a standalone with source
so that it can be used with other compilers.

> passing an environment modified with putenv() to child process

putenv() doesn't modify directly the image of the environment passed to
you by DOS, and it doesn't maintain env vars in the DOS format internally.
If you start the child process using your library spawn() and/or exec()
functions, any putenv()-based environment mods should be passed
automatically. If you must use Pexec() for some reason, then you also
must do manually what the spawn()/exec() functions do internally:
assemble the strings pointed to by the environ[] array entries into a
DOS-format env array, then pass the array via Pexec().

If you want, I can post or email some code to do that.

Source record: 43559

The compiler that comes to mind to meet all those specifications is Lattice C v5.51. It claims to read/link Sozobon-style object modules, but I haven't personally confirmed that yet. It definately does everything else on your list.

Sozobon v.20 will handle everything on your list except prototypes, I think. But, it's dumb about other common extensions toward ANSI too. (Like, it doesn't understand what a void pointer is.)

HSC won't support long external names for a few months, and won't support prototypes in the foreseeable future at the rate I'm going with it.

We have had some mail problems here at Nyx recently, and I'm afraid that if you've sent me mail in the past week I may not have received it, and it may not have bounced back at you either.

If you've sent me a bug report for Sozobon/HSC/GemFast in the past week or two, and you haven't gotten a reply back from me, please resend it. The proper address nowadays is ilepore@nyx.cs.du.edu. If that fails for some reason, you can try ilepore@newnyx.cs.du.edu. What CAN'T use anymore is @isis.cs.du.edu (isis is now a file server for nyx).

As I was talking to Jeff (in email) about, the statement "the rest runs
at 16MHz" is rather misleading. Sure, you are limited to about 14MHz with 70ns
DRAM (there are now 1MB60ns so that would give you 16MHz tho), and so the
memory does run at roughly 14MHz (not counting time waiting till next 32MHz
clock tick), but whole point of my post was: so what? Every other machine is
faced with this same limitation, yet no one else says "Gee, that there Mac runs
with a 40Mhz '030, but the rest of it runs at 14MHz". If a company were to
make a 1MBx8x30ns simm, and someone were to make a card to put into the TT that
could handle that, then catagorizing the "rest of the system running at 16Mhz"
would be wrong - which is the reason why no one else describes other systems
this way. They have the same problem, and ability to (eventually) over come
it.

About the CPU having to slow down: This is not true. Remember, the
'030, like the 80486 and the '040, have a built in cache that is fed by a
pre-fetch mechanism. That way it usually requests the data while it is
processing the previous instruction/data. Also, it has its own MMU so that
it accepts the data as it is presented on the bus without (necessarily) wasting
processor cycles for it to be loaded into cache.

BTW, I am pretty sure that a "wait-state" induces a full clock-cycle
wait - it must wait until the next falling (rising?) of the clock before it
can accept the data, if it is ready.

>This is where cache comes in (but that's a whole nuther story)!

Sure, but then again, you are talking about faster memory, that for
cache hits, does operate at (assuming 30ns cache memory) 32MHz.

>Also, keep in mind that the external clock freq. of a CPU is a deceiving
>measure CPU speed since the CPU will divide it internally by two, four, etc.

Very true - I believe that the '030 has a divide by two, but the '040
does not have a internal divider (like the 80486) - or rather it has a divide

by one :).

>Sorry, just in the rambling mood I guess.

Fast RAM is not like STram. TT (fast) RAM does not have to deal with
video or some of the other devices (I believe the SCSI port) and so it can be
accessed at the full 32MHz (memory speed allowing). It is 32-bits wide.

ST RAM is shared with video (it is on a different data bus I believe)
and it is arranged in a 64-bit fashion. The CPU must share ST RAM in 250ns
time slices with video.

TT ram is MUCH faster.

You can get a 2MB or 8MB ST ram board (usually about $250 and $750
I think). You can get an Atari 16MB TT ram board (way expensive) or you
can buy one of the TT boards (GE Soft?) from Germany that can hold up to
32MB for ~$500 (unpopulated).

> Sorry, what is a "_CPU cookie" - I have the Laser-C package and I don't recall
> this. Is it an asm toy ?

There is an area of memory set aside for programs to install information
about themselves. Each bit of information is called a "cookie", and consists
of a 4 byte "name" and a 4 byte value. For example, MiNT installs a cookie
with the name 'MiNT' and the version number of the program as the value.

The operating system (TOS 1.06 or higher) automatically installs some cookies
when starting up. One of those cookies has the name '_CPU' and has a value
which indicates which kind of CPU is running.

2772. ESDI drive on ICD solved

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-16 06:30:43 UTC
From: sytang@lamar.ColoState.EDU
Message-ID: <Jul16.063043.70134@yuma.ACNS.ColoState.EDU>
Source record: 43569

Some weeks ago I asked any one used ESDI drive with ICD host adaptor, and some said no. And only Mr. William Mago said he has one working, so I asked him for detail on his setup. Now I have an ESDI drive working with ICD too.

Yes, ESDI drive can be used with ICD if one also has Emulex MD21 ESDI-SCSI adapter. It works very well, my HP97532 gives 543KB/sec average transfer rate and 23ms average access time according to the HDRATE from ICD software. The problem I had was cause the ACB4520 probably did not implement the SCSI right and ICD did take that card into account so it doesn't function right. (the card passed the self test, and the drive is the HP drive above).

I asked about it on BIX, and John Townsend of Atari supplied the following
helpful example:

==========================
atari.st/tech #4341, from towns, 2454 chars, Wed Jul 15 19:40:42 1992
This is a comment to message 4339.
--------------------------
Just so happens that I have some code I saved off of GEnie. Here goes:

------------
Category 3, Topic 31
Message 41 Thu Feb 06, 1992
STARFALL [Alan] at 04:43 EST

Terry, to read the keyboard you need to steal one of the kbdvbase
vectors. You can do it with code something like this:

#include <osbind.h>
#include <xbios.h>

#define UP 1
#define DOWN 2
#define LEFT 4
#define RIGHT 8
#define FIRE 0x80

unsigned char joydata[3];
int flag;

void joystick_reader(packet)
char *packet;
{
joydata[0] = *packet++; /* Get joystick packet, one byte at */
joydata[1] = *packet++; /* a time, since it could be at an */
joydata[2] = *packet; /* odd address */
flag = 1; /* Indicate a valid packet */
}

main()
{
register struct kbdvbase *kp;
register void (*old_joyvec)();
```

```
int code;

kp = Kbdvbase(); /* Get pointer to IKBD vectors */
flag = 0; /* No valid packet yet */
old_joyvec = kp->kb_joyvec; /* Save old vector */
kp->kb_joyvec = joystick_reader; /* Install new routine */
Ikbdws(0, "\024"); /* Turn on joystick reporting */

while (1) {
while (!flag && !Cconis()) /* Wait for event */
;
if (Cconis()) break; /* Quit if a key pressed */
code = joydata[2];
flag = 0;
if (code & UP) printf("up ");
if (code & DOWN) printf("down ");
if (code & LEFT) printf("left ");
if (code & RIGHT) printf("right ");
if (code & FIRE) printf("fire ");
printf("\n");
}
Crawcin(); /* Get key that was pressed */

Ikbdws(0, "\010"); /* Turn mouse back on */
kp->kb_joyvec = old_joyvec; /* Restore the old vector! */
}
```

Note that this program will only read the joystick in port one. Be careful about nudging the mouse, though, as this will mess up the joystic. It's possible to read both ports seperately, but this is trickier. This mode lets the joystick return a packet whenever it changes state. There are other modes which only send the joystick state when specifically requested, or sends the state a regular intervals, whether the joystick has moved or not.

```
/
/ * / Alan
* *
```

Anyway, I hope this helps.

Oops, I botched it:

> Pexec env --> "FOO=\0BAR\0ARRGH=\0GULP\0\0"

should read

Pexec env --> "FOO=BAR\0ARRGH=GULP\0\0"

Only the initial $PATH looks like "PATH=\0C:\\\0".
(And a right nuisance it is.)

Hello,
I would like to know several things.

1) Where can I get ROM v1.4?
2) Why is it better than the older versions?
3) How much does it cost?

If you need the info, I have a 1040STf I bought in
1988. Please email me or post here. Thanks in advance
to those who answer.

2778. Re: HELP ME - INFO NEEDED

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-16 15:19:59 UTC
From: monnier@disuns2.epfl.ch
Message-ID: <1992Jul16.171959@disuns2.epfl.ch>
Source record: 43578

In article <l69hdoINN3rs@aludra.usc.edu>, baffoni@aludra.usc.edu (Juxtaposer) writes:
: As I was talking to Jeff (in email) about, the statement "the rest runs
: at 16MHz" is rather misleading. Sure, you are limited to about 14MHz with 70ns
: DRAM (there are now 1MB60ns so that would give you 16MHz tho), and so the
: memory does run at roughly 14MHz (not counting time waiting till next 32MHz
: clock tick), but whole point of my post was: so what? Every other machine is
: faced with this same limitation, yet no one else says "Gee, that there Mac runs
: with a 40Mhz '030, but the rest of it runs at 14MHz". If a company were to
: make a 1MBx8x30ns simm, and someone were to make a card to put into the TT that
: could handle that, then catagorizing the "rest of the system running at 16Mhz"
: would be wrong - which is the reason why no one else describes other systems
: this way. They have the same problem, and ability to (eventually) over come
: it.

Just a little precision (although not so much important): 70ns is the time to get
the data (access time) but the cyle time is 1.5 to 2 times greater cause a DRAM
has to rest for a while between each access (I'm currently speaking of pure RAS
access). During that time, the DRAM writes back (refresh) the entire row previously
selected.
Anyway, with 70ns DRAM, you can get 16Mhz access through burst access: you first
select a row and then access several datas in that row: you then use the CAS access
and cyle times (access: about 40ns, cycle: about 60ns).

Personnally, I think the bigger problem with TT memory is that there is no
(the 512 internal bytes apart) cache. A fast cache (no wait states) could
add about 30-50% processing power, I think ! (well I'm maybe a bit optimistic)

Large screen monitors - I too think Atari's TTM195 is a very nice one;
shame its not grey-scale.
In Switzerland, Germany, even UK - you can get EIZOs (not Eico); very nice indeed,
especially the big colour ones.

Pleas, don't use separate DRAM chips: SIMMS are not more expensive, they
include condensators (100nF I believe) and they need LESS cabling !

I don't have the SIMMS pinout (nor any other pinout) right at hand but:

RAS1 (or RAS0 depending on the bank you want to use) from MMU
to RAS of SIMMS (the same signal for both).
address pins A0-A9 from MMU (or other memory bank)
to both SIMMS (in parallel).
data D0-D7 from old memory bank or (better) 74LS373 to one SIMM
data D8-D15 from the other 74LS373 to the other SIMM.
CASH1 (or CASH0 depending on RAS choice) from MMU to the CAS of
the SIMM with data 8-15.
CASL1 (or CASL0) from MMU to CAS of SIMM with D0-D7.

don't forget power cables (big cables or(and) better: double power
cabling to avoid flickering)

And last: there should be some resistors (of 33 or 68 Ohms) between the
MMU and the SIMMs for CAS and RAS signal (maybe not necessary for RAS).
So if you take these signals directly from MMU, add a resistor inbetween.

If you have problems, don't forget: you've got another MEM bank already
installed: just look there (with some ohmmeter for example) how it is
connected !

Howard: I think what you're witnessing is a slight variance between
the sending and receiving system's UART clocks. The reason that the
MFP's /0 mode is not recommended for async is that, in async, you
don't have a common clock signal between the sender and receiver. The
receiver detects bits by watching for transitions on the input signal,
and if your clock rate is the same as the bit rate, you'd better be
exactly in step or you'll eventually miss a transition. To illustrate:

Sample time: V V V V V V

_______ _______ _______
Signal: ___1___| 2 |___3___| 4 |___5___| 6 |___7___

Note how transition #5 gets missed, since the samples around it both
catch the input signal in a high state.

In /16 mode, the receiver can sample the line 16 times per bit (the
"sample" line would be full of "V"s in /8 mode) and will therefore not

miss a transition.

In /0 mode you'd also have problems if you wanted/needed to use 1.5 stop bits. 1.5 stop bits may sound impossible ("how can you send half a bit?"), but it simply means that the line is held in an "on" state for the time it takes to send 1.5 bits. In /16 mode, this means that an "on" condition that lasts for 24 samples is a start bit, so the UART begins shifting the input bits into its input register.

I suspect you'd see a similar situation (albeit with a slight change in the error interval) if you communicated with a different brand of machine.

2787. Summary: memory upgrade for ST2 w/o extra cards

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-16 18:07:56 UTC
From: kruel@wpcst1.phys-chemie.uni-wuerzburg.dbp.de
Message-ID: <H.o7vhhwGX41E@wpcst1.phys-chemie.uni-wuerzburg.dbp.de>
Source record: 43585

10 days ago I asked about the possibility to upgrade the old Mega ST2
and ST1 to 4 Megs by simply soldering in new RAM chips into the free
positions.

Here are some answers I got. Thanks to all of you who responded.

First the summary:

- Mega ST1 cannot be upgraded this way at all
- Mega ST2 can be upgraded, if
- the MMU can address 4 MB (sometimes not the case)
- free places for sockets are available
- a complete instruction guide for doing is included (see below)
- if you don't need a new MMU, it's far cheaper than a commercially
offered upgrade board.

----------------------------------< next one >--------------------------

Jonathan Whitcomb <whitcomb%aurgate@mcnc.org> gives us a complete
instruction guide:

> Here's an article I downloaded from GEnie which I used to upgrade my
> Mega 2 to a Mega 4. It should answer most of your questions.

----------------------------------< begin of article >------------
So you have a Mega 2, but would like 4 megs of memory. In
the eyes of Atari, you should sell your Mega 2 and buy a Mega 4.
However, I disagree that you should have to do this, and thus
decided to upgrade "the hard way" instead. If you have had no
soldering or de-soldering experience this project is not for you.
There are 18 pins on each chip socket, with 16 chips. That's 288
connections, each one has to be de-soldered and then re-soldered
perfectly to work well. There are also a few resistors that you
must add for a successful upgrade.

And now for some legal mumbo-jumbo to keep me off the hook:

This upgrade WILL violate any and all warranties on
this computer product. I do not promise that this

upgrade will work, and hold no responsibilities to the
equipment or person doing this upgrade.

Ok, enough of that. You will need the following products to
do this upgrade:

3-33 ohm 1/4 5% resistors
16-1 Megabyte chips of the same speed as the present ones in
your mega
16-18 pin low-profile chip sockets

also

a pair of needle-nose pliers
a pair of small wire cutters
a 25-35 watt soldering iron
a 30-50 watt solder-sucker iron -or- solder braid
a roll of miniature solder
a small flathead screwdriver
a medium-sized phillips screwdriver
a can of solder flux remover
a ohm-meter to check for shorts

* And most important.... A GROUND (electrical) & A CEMENT OR
TILE FLOOR to work on (So that you do not zap all these expensive
parts, or your computer).

Steps in upgrading a Mega 2 to a Mega 4:

1. Open up plastic case by removing ALL the screws on the bottom
of the case first. Then remove the top. Be careful with the
clock cable, it is very fragile.

2. Bend the RF shield tabs so that they are strait, and then
remove the shield. Note, there is a tab underneath the disk
drive that is hard to see (and get to).

3. Unplug the internal disk drive from power supply and drive

bus. To remove the power supply plug, use a small
screwdriver to pry the connector clasp up.

4. Unscrew the power supply, and unplug it from the board and
remove.

5. Turn the computer so that the expansion ports face you.
Unscrew all of the screw posts. This is required for you to
be able to remove the bottom RF shield.

6. Now, remove the circuit board from the bottom of the plastic
case.

7. Remove the bottom RF shield from the circuit board so that
you can access the bottom.

8. Turn over the circuit board so that you can start solder-sucking out the solder where the chip sockets will go. This is the trickiest part of the operation. If you have never done this before, find someone else to do it for you (or at least show you how). There will be 16 blank chip areas, this is where your sockets will go.

9. Now, check for any shorts that may have developed in solder-sucking. If there are any, correct them before continuing.

10. Spray some solder flux remover on the back of the board (over a sink, or paper towels). This will allow for a better solder contact.

11. Plug the power supply back into the board and plug in a monitor (DO THIS ON A NON-CONDUCTIVE SURFACE!). Turn the unit on. You should get the normal GEM screen in 30 seconds or so. You of course will not see any drive icons, as you have no drive attached.

>> If you do not get this screen, but instead get bombs or wierd patterns on the screen, turn off the computer immediately and check for shorts. Correct these before continuing.

12. Take the power supply back out (I bet you are getting good at this).

13. Now, install the 16, 18-pin chip sockets into the newly solder-sucked holes. Make sure to put the notches in the same direction as marked on the PC board. A trick to keep the sockets in the holes while turning over the board is to bend opposite corner pins outward. You may wish to do one socket at a time, rather than putting them all in and then soldering them all at once. This is your choice :-)

14. Again, put the power supply back in to check for shorts. After checking and correcting problems, remove the power supply.

15. Now you need to install 3, 33 ohm 1/4 watt resistors in the empty resistor sockets located near the chip banks (normally toward the inside of the Mega). The direction does not matter, but they look better if your new resistor's stripes match the present ones. Put them in snug to the board, and then clip off the excess leads.

16. Again, use the solder flux remover to clean up the PC board. This will make your project look more professional, and keep the flux from attracting dust.

17. Now, install all of the 1 megabyte chips, making sure to put the notch in the correct position (Normally pointing to the

middle of the Mega). Usually chips come too wide to fit in
sockets, use the corner of a desk to gently bend all the pins
on one side at the same time. Be very careful not to bend
any pins inserting them into the sockets. If you do, use the
needle-nose pliers (after touching them to a ground) to
straighten the pins.

18. Install the power supply again and test for shorts. After
all tests out ok, re-assemble the computer in exactly the
reverse that you took it apart.

19. You now have a mega 4! Enjoy. If you have any problems,
leave me a message on GEnie to BDHALL.

------------------------------< end >----------------------------------

Just one further note: You can test your MMU if you put it into an
already upgraded ST or an ST4; if it works, then you're oK.

The price for the upgrade is the price for the SIMMs (ca. 120-160 DM =
80-105 US $) and the sockets + some minor stuff.
This is considerably less than the commonly offered upgrade boards for
around 350-400 DM (230-260 US $).

In case you need a new MMU, the I grabbed out a price of DM 95 (60 US $).

Enjoy,
Thomas

2788. Dream Machine needs video!

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-16 18:37:56 UTC
From: skolodzieski@vaxc.stevens-tech.edu
Message-ID: <1992Jul16.133756.1@vaxc.stevens-tech.edu>
Source record: 43583
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

Hello,

I am finnaly approaching my dream machine status. I have the following:

1. circa 1986 1040st upgraded to 4 meg.
2. a Tower Power (german) Tower case and Seperate Keyboard.
3. A Tiny Turbo 030 (50MHz) with 8 additional meg of ram.
4. Virtual Memory manager for the 030 card.

All I need to put me over the edge is a good video card. A friend of mine has a Crazy Dots 8, and a Eizo 6500 21" (1660x1200) grey scale monitor, and It looks better than one could possibly imagine. Unfortuantly Crazy Dots is either MegaBus or VME.

Does anyone know of a good quality vide add on card for a plain 1040. Space is not a problem as I have the tower case!

P.S.

I promise that tomorrow the new port of Emacs 18.58 will be on a.a.a.e, I just need to polish the doc a bit more. By the way I will put it in the directory new/ with the name "1858b-d3.zoo".

cheers,
scott kolodzieski

2789. GCR on TT (Summary)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-16 23:13:38 UTC
From: ens@ccu.umanitoba.ca
Message-ID: <1992Jul16.231338.24971@ccu.umanitoba.ca>
Source record: 43588
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Thanks to everyone that wrote with suggestions on getting my GCR working on my TT. The floppy drive still doesn't work with MAC disks but otherwise Spectre 3.0 is now working from a hard drive; I have to carry the GCR over to a 1040 to convert mac disks to spectre format and then use them on the TT. Hopefully Spectre 3.1 will be available soon to correct this.

Here are a few things I learned that might be useful to other people in similar situations:

1) Spectre does not have to pass the GCR floppy test to work on a TT. If you are booting from a working hard drive plugged into the ACSI port, it should boot up all right. This is true without the modification recommended by gadgets. I was in fact using a hard drive from the beginning but without success because of item 2 below.

2) Spectre does not work at all on a TT with more than 4 Mbytes ST RAM. I discovered this when I tried it on a different TT that had only 4 Mbyte and it worked; mine has 10 Mbytes. I have temporarily swapped memory boards since so I can use Spectre. Someone suggested I try to trick Spectre by replacing the value of the global that indicates the top-of-memory with the value of 4 Mbytes. This might work but I rec'd the suggestion after I swapped boards and haven't had a chance to try it yet.

3) Spectre 3 is not bothered by extra TT RAM, but it also does not benefit from it; I have 32 Mbytes and it works OK (apart from the floppy drive).

4) The recommended modification to the GCR to make it work with MAC floppies on a TT didn't make it make it work on mine. That may be because I have a 1.4 Mbyte floppy drive. As mentioned above, I use Spectre on a TT with a hard drive and Spectre-format floppies. Some people have had success with external 720K floppy drives. (Can anyone tell me how to convert an internal floppy drive from a now defunct 1040 to work as an external drive on my TT?)

5) After the recommended modification for TT use, my GCR did not initially work on a regular 1040. However, by shorting out the capacitor it could again be used on a 1040. (It also works on the TT with the capacitor shorted if MAC floppy disks are not used.)

These days the cost of buying the extra memory required for running
GCC is probably less than that of purchasing any commercial C compiler.
Perhaps you shouldn't dismiss GCC out of hand...

Here are some quotes from a motorola manual on the MC68901..

When the clock is in the /0 mode, synchronization must be accomplished
externally. The receiver will sample the serial data on the rising edge of

the receiver clock. In the /16 clock mode, the data is sampled at the mid-bit time to increase transient noise rejection..

Also when in /16 clock mode , the USART resynchronization logic is enabled, This logic increases the channel's clock skew tolerance. When a valid transition is detected, an internal counter is reset to state zero. Transition checking is then inhibited until state four. Then at state eight, the previous state of the transition checking logic is clocked into the receive shift register..

The /0 clock mode is only ment for Synchronous use...

A small note, I did some work with a standard CMOS UART and managed to get it to work at a data rate of 350k, this was not part of a PC, but a controler that I was designing, but as it was only a one off it did not matter..

So I hope this is of help to you all...

Roger..... sheppard_r@kosmos.wcc.govt.nz

2792. Re: Joystick programming help needed

Newsgroup: comp.sys.atari.st.tech

Ian posted source for reading a joystick. Unfortunately, it only reads
one stick. Here is a article with accompaning source for reading BOTH
ports as sticks....

_______CUT_HERE___8<_____________________

Extracted from the March issue of the High Sierra Atari User Group JOURNAL.

JOYSTICKS SOLVED

About a month ago my game program was to the point where joystick
input was needed to control the good guys. However no-one including
the ever supportive Megamax could lead me to a working joystick
program. I have since solved the mystery.

First a quick look at the addressing. The Atari Developers Kit is
correct and the joystick report is 16 bits long. Except that the Atari
is a 16 bit machine and the I.B.M is 8 bits. Making the joystick
report on the Atari come in one 16 bit "int". Rather than two 8 bit
reports consisting of LSB (Least Significate Byte) and MSB (Most
Significate Byte).

The address that the joystick report is stored is 3592 (decimal)
or 0xE08 (hex). So the pointer "*js" equals address 3592. However
before we can poll the sticks we must make the calls Bconout(4,0x12)
and Bconout(4,0x14). Bconout(4,0x12) shuts of the mouse reporting
and allows us to read joystick 0 (mouse port 0). Bconout(4,0x14) sets
the intelligent keyboard to the default of poll each joystick report.
Even though it is the default it must be called to get both sticks.

The joystick report will generate numbers like (-32512) and 1.
If you look at these numbers in Hex it makes sense. The way that the
reports is stored is:

xxxxAABB where B = stick 1 and A = stick 0

Looking at (-32512) this is what we see:

FFFF8100 hexidecimal number of (-32512) decimal
81 hex = 129 decimal stick is up and firing
00 hex = 0 decimal stick is normal

So if the stick returned (-32255):
FFFF8201 hexidecimal number of (-32255) decimal

82 hex = 130 decimal stick is down and firing
01 hex = 1 decimal stick is up

The main part of this program is stripping unused or unneeded bits. To get stick 1 (mouse port 1) just "AND" the returned value with 255 decimal or 0xFF hex. The second stick is a little more involved. First strip off the first joystick by "ANDING" the value with 0xFF00 hex or 65,280 decimal. Then divide by 0x100 hex or 256 decimal. This shifts the bits right. And finally look at first stick again and that is the correct value. This is the values and direction according to this program:

NORMAL WITH FIRE BUTTON
1 129
5 | 9 133 | 137
\ | / \ | /
4 ----- 8 132 ----- 136
/ | \ / | \
6 | 10 134 | 138
2 130
center = 0 center = 128

The final call is to be used before you exit the program and that is Bconout(4,0x08). This turns the mouse back on.

There is another little "gem" in this program and that is the character routine. I do like input from the "user" but I don't want to stop all computations while I wait for the "user". So the call character = Cconis() tells me if there is a character ready to use. I then test character against (-1) (-1 means a character is ready) and if it is true the character = Crawio(0xFF) giving character a real character value.

I hope that this helps. As my program develops and more unpublished secrets are revealed to me I will share them with you. If you would like to see more articles like this please tell the editor. If you have further questions please call Michael Wood at 673-4837.

Sozobon 2.0 is your man. Matches all of the above. Should be on BART.

>Would be nice:
> ANSI prototyping (TC)

Don't think it supports that yet.

> 32 character object names (TC)

I think Sozobon 2.0 is fairly unrestricted in the symbol length dept
(fnargh, fnargh :-) in that uses extra weird symbols that other DRI linkers
will ignore which contain that extra text beyond the initial eight.

2794. Re: Midi from the serial port?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-17 18:38:33 UTC
From: shiv@bnr.ca
Message-ID: <1992Jul17.183833.19499@bmerh85.bnr.ca>
Source record: 43492

C-lab offers EXPORT for Creator/Notator which gives 3 MIDI ports from the Atari serial port ! Its quite expensive considering its just a little hunk of plastic. I've been tempted to open it up and see whats in there. I doubt it contains more than 2 or 3 chips and one or other components.

I also own a Mac and a friend built a MIDI interface for the Mac's serial port with $5 worth of parts. If you can't get anymore info, email me and I'll see about getting a circuit diagram of the Mac's serial to MIDI interface - you should be able to easily adapt it to the Atari.

cheers,

Shiv

I believe that JRI (John Russell Inc.) in California has a Megabus mod for
1040s. You might want to contact him; unfortunately, I don't have his number.
Anyone else have it?

I've only heard rumors of this product. I may be incorrect. But JRI usually
has very unusual products that not many people hear about.

Well, since no one wanted to tell me the answer I found it myself
in an artcle by Doug Tarico, Weak CHIPS in ST or something like that.

Back on May 15, Doug pointed out two weak buffer chips

They are the 74LS373 chips. I put in 74HCT373 and now the machine
almost never bombs.

Thanks Doug!!!

From: mfg@gmd.de
Message-ID: <mfg.711497130@gmd.de>
Source record: 43500

I am writing on a xterm-clone (DA) for GEM and MiNT (0.94) like BG.ACC but with additional features (GDOS-fonts, copy-and-paste, history,...) Now my problem: I am creating a pty per window, named "U:/PIPE/PTYx". Later I start a TTP with Pexec(100, ...) from the DA. All standard streams are forced to this pty opend as client. Everything works fine until I change my GEM main program (for example calling a GEM-Program for Gemini). From this moment on the DA begins reading nonsens from the pty (maybe EOFs) until I go back to the program from which I launched the TTP in the terminal window. Now all works again. Why ??? Is it a problem of process groups?

Thanks Martin
(by the way: if the program is completed, it will be free ;-))

Martin F. Gergeleit <mfg@gmdzi.gmd.de>

> So, what's the best way to declare the variable within the structure? Is
> merely making it a char * sufficient, or do I need to make it static char *?

ok. i'll bite: you really should be reading a good C book:

you certainly do not want to make anything static inside a
structure (in fact i am not sure if you even can). a static modifier
just controls the scope of the declared object. for instance anything
declared static at the module level (that is outside of any function)
is visible only in the module (file) in which it appears. if a
variable is declared static, then in addition to the scope semantics,
it also makes it persistant. fields of a structure are not object/variables,
so you cannot put the static modifier there.

to answer your question: i guess the best way to optionally allocate
some fileds is to declare the fields as pointers to the type you want,
and malloc() them on demand. for instance

```
typedef struct _window {
int x,y,w,h;
....
char *name;
} *Window;
#define WindowSize sizeof(struct _window)

/* return an instance of Window */
Window new_window()
{
Window w = (Window *) malloc(WindowSize);

if(!w) fail();
```

```
bzero(w, WindowSize);
return w;
}

/* fill in the name field */

wx_name(ws,str)
Window ws;
char *str;
{
if(!(ws->name = strdup(str)))
fail();
}
```

Another way to approach this is to store the name in the structure itself.

```
typedef struct _window {
int x,y,w,h;
....
char name[1];
} *Window;
#define WindowSize sizeof(struct _window)

/* return an instance of Window */
Window new_window(wname)
char *wname;
{
Window w = (Window *) malloc(WindowSize + strlen(wname));
/* In WindowSize we have accounted for 1 byte needed for the final \0
needed to store the string , so we dont need strlen(wname)+1 above */

if(!w) fail();

bzero(w, WindowSize);
strcpy(w->name, wname);
return w;
}
```

in this scheme you can only initialize the name field when the window instance is created. the advantage is that you avoid the over head of one char pointer.

Does anybody know what the argument given to the "STOP" instruction in
Motorola 68000 assembly is for? Any information would be appreciated.
E-mailed responses prefered.

Well, if you had bothered to look it up, you would find that the argument
is loaded into the status register (the same as a MOVE data,SR instruction).

: Well, if you had bothered to look it up, you would find that the argument
: is loaded into the status register (the same as a MOVE data,SR instruction).

And if you had bothered to read his letter you would have found out
that he wanted E-mail answers. ;-)

Also, the STOP instruction is QUITE a lot different from a normal
MOVE to SR (for example: apart from the halting of the processor
that STOP does, the STOP only takes immediate data while MOVE to
SR takes any effective address). Maybe the guy who asked the
question didn't have any book describing the STOP instruction. If
I would have been in his place (and not knowing all Moto-syntax
by hand :-) I too would have asked this newsgroup. Please, don't
take this as a flame!

BTW, I emailed him a _quite_ complete explanation a couple of hours
ago. :)

2806. GFA Basic help needed

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-20 03:21:12 UTC
From: cinnanum@mentor.cc.purdue.edu
Message-ID: <54512@mentor.cc.purdue.edu>
Source record: 43507

I have been trying to get a simple program to compile and run but the program keeps returning an error 008 when it gets to the open statement. It runs fine under the interpreter and under the GFA Basic Run Only program. I am using versioni 3.5 of GFA on a 520 STFM w/1 meg and TOS 1.0. What is the difference between the run only program and a compiled program?

2807. Emacs 18.58 REALEASED!

Date: 1992-07-20 04:16:10 UTC
From: skolodzieski@vaxc.stevens-tech.edu
Message-ID: <1992Jul19.231610.1@vaxc.stevens-tech.edu>
Source record: 43506
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hello,

The wait is over! I just posted emacs 18.58 to aatri.archive.umich.edu!

The file names are:

1. 1858b-d3.zoo - everything needed to install/build a working
EMACS. Includes docs in LaTeX and ASCII form.

2. 1858d-d3.zoo - Just the docs from the above archive. If you
are not sure about EMACS get this file and
read the docs please!

I spent several weeks writing and editing the doc file. It is now 16 pages
with a table of contents and contains a wealth of information. It covers
installation and usage along with a lot of general information.

I will post source code at some point, I need to work on cleaning it
up a bit and documentingh some of the changes that I have made to it.

cheers,

scott kolodzieski
scott@sparc1.stevens-tech.edu

| >or 0xE08 (hex).
|
| Is this guaranteed not to change? I doubt it, so I'd stay away from
| this solution to the problem.
|
| Dave Baggett
| dmb@wam.umd.edu

With the way Atari is running things, it may not matter for long :D :D!

But seriously, it's a simple demo, so it wouldn't be too much trouble
to test it on various systems and TOS versions. (I've tested it on
a 1040STf w/ 1meg && TOS 1.0).

No, it is not a "perfect" or "elegant" solution, but it should get him
started until he forks over the develp. funds or gets help from
others (or he discovers a solution to this).

Hopefully, someone more knowledgeable can post a more complete
solution to this (IMHO basic) problem of reading those ports.
That's what this newsgroup is all about, right?

Enough,
Rich K.

>works again. Why ??? Is it a problem of process groups?
>
Hello Martin,

under MiNT the file handles are local to a process. From the point of view
of MiNT a DA is not an extra process, because the DA multitasking is done
by the AES. If you launch a new GEM program, a new process is started an
the DA cant access its former opened files. This happens the same way,
when you open a file under a GEM program and leave it (the file is closed
by MiNT). This is no MiNT bug, instead it is a feature that each process
can open 32 files...

A second problem occurs with the memory, the DA allocats while another GEM
pogram is running. If the process terminates, the memory is freed. This
also happens to memory that you malloced indirectly, like loading GDOS-
fonts or opening a new VDI workstation...

And the last big problem that you will meet (when continuing in the DA/xterm-
quest...) is that a process that was started under the desktop in your xterm
clone is in the sleeping state after you start a new GEM process ;-)
The only way around these problems is starting a sub process in you DA. Now
the process is a paralell process to the GEM desktop and you have your
own file handles and memory ownership... You may look in the source of
the 'old' BGACC how to start a sub process.

Under MultiTOS the DAs are full processes and all the above problems don't
occur. It would be wise, if the DA could also be started as APP and if all
MultiTOS features (like scrolling in 'back' windows...) are supported.

Greetings, Karsten

PS: You see you are not the only one, who programmed such a xterm-clone...
But the more programs there are, the better is the chance to find a
really good one ;-)

>serial port ! Its quite expensive considering its just a little hunk of plastic.

You forget one major feature of EXPORT:
It allows you to send information to one MIDI port only, so giving you
3 * 16 = 48 MIDI channels! So this thing needs some more intelligence,
and this may be the reason of its price.

Are you SURE there are some that can't get more than 2M ??????

I'm MOST surprised: I know there were some MMUs that can't deal with
2 different size banks (that's 2.5M) but ones that only use 1
bank..?

In this case how do third party boards enable you to get to 4M ?
(as I don't know any that sells MMUs with their extension (not
mentioning the special cases that enable you to go up to 15M))

2817. Unixmode

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-20 13:18:54 UTC
From: monnier@disuns2.epfl.ch
Message-ID: <1992Jul20.151854@disuns2.epfl.ch>
Source record: 43520

I just installed Emacs 18.58: this time, I used Unixmode: that's
much better indeed !
But a little problem arose: I usually use less1.7 to view files.
when I want to view a file named ReadMe (for example), I have to
write 'less ReadMe'; 'less readme' doesn't work (although it is
under this name that gemdos stores the file)

How come ?
Is it normal ?
In this case I'm quite unhappy cause it is not so easy to remember
the exact name (as ls shows normal gemdos names).
Couldn't Unixmode be introduced as another filesystem: this way
translation would always occur: for ls and all other apps)
I know I can mount a Minix partition but: my hard drive has a
few errors: 1600 bad sectors in the first 26M and 0 good sector
in the 20M left ! And I don't know if Minix partition can work
with such a mess (Spectre can't).

|> the control if I move it. (The job was to allow moving of the mouse
|> since the system is sending...)
|>
```

Your problem is caused by the fact that the keyboard ACIA chip uses
levels to trigger interupts while the MFP chip is edge trigered.

What happens is that when the ACIA wishes to interupt the 68000 it pulls
its interupt line low. The MFP chip sees this negative going edge and
interupts the 68000. In the normal couse of events the interupt routine
will reset the ACIA and the MFP and everything will be okay.

However if you disable the keyboard interupt at the MFP and a keyboard interupt
arrives the ACIA will not be reset - Its IRQ line will be stuck at zero - no
more negative going edges will be generated and no more keyboard interupts
will be generated even when you re-enable the keyboard interupt. Thus the ST
appears to lock up.

One thing you might try is to _mask_ rather than disable the keyboard interupt
so if a keyboard interupt arrives the interupt routine will still be called
to tidy things up _after_ you unmask the interupt.

If you really worried about accurate timing you should do the same thing
with the system clock (as well as disable the VBI of course!); ie from supervisor mode

```
IMRB equ $FFFFFA15 ; interupt mask register B

and.b #$9F,IMRB ; to mask ikbd & timerC interupts
```

```
ori.b #$60,IMRB ; to unmask ikbd & timerC interupts
```

An alternative would be to disable the keyboard interupt directly at the ACIA.

Steven

2819. Mouse not working on 520ST

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-20 15:28:44 UTC
From: rempel@skorpio.usask.ca
Message-ID: <1992Jul20.152844.20860@access.usask.ca>
Source record: 43521

I've got a problem with the mouse operations on my 520ST. When I boot up, the mouse cursor starts off in the center of the screen. Then, as I use my mouse to move around, I can go up or down okay, but if I move the mouse left or right, the mouse cursor just moves to the left. After about 5 seconds of continuous mouse moving, the mouse cursor is at the left edge of the screen and the only way to bring it back is to use the Alt-arrow keys. Does anybody know where the problem might reside, and how it might be fixed?

I took the mouse apart once, and in the process, I might have been a little rough taking off the 8-pin inline connector from the circuit board inside the mouse. It could be that some of these wires are damaged. Might that be responsible for this problem?

If the problem lies with the mouse (and I hope it does, 'cause I think that's easier to fix), then I guess I'll have to replace it. But ST mice are hard to come by in Saskatoon. I heard that Amiga mice can be hooked up to STs with a few modifications. Does anybody know where I could find out how to do this?

Thanks.

Thank you for this hint!

You are right with the analysis of my problem. But I think there is another
solution to it. With MiNTs call Fcntl(..., F_SETFD) you can force a file
handle to be inherited to Pexeced childs. If the pty now is created at DAs boot-
time, it will be inherited to all GEM programs (and their DAs).

BY THE WAY: THE DESCRIPTION OF THE F_SETFD OPTION OF FCNTL IS BUGGY. The flag
has to be 0 to make childs inherit the file handle, not 1 as described in the
0.94 man pages.

These two problems should be handled by starting the TTP with the mode 100 of
MiNTs Pexec, I think. (correct me if I'm wrong).

>Under MultiTOS the DAs are full processes and all the above problems don't

I will try to write clean code, that all I can promise. I have not see any
offical MultiTOS Doc (besides rumours in the "ST-Computer" magazine).
Unfortunatly, I am not a "real" developer. (You will recognize them by their
1040-like boxes with the words "Falcon" on top.)

Since there seems to be alot of objection to this idea, might I suggest a different approach to the problem. Instead of bringing the mouse to the dialogue, why not bring the dialogue to the mouse? That way, there wouldn't be any of this confusing mouse jumping.

I like the idea of trying to bring the dialogue and the mouse closer together. Speaking from experience, I find it _really_ annoying having to drag the mouse all the way across the screen (here at work, a 1280 x 1024 screen) to click on a button. I do find the `jumping mouse' to be a little disorienting (I start moving the mouse, anyway), so perhaps doing it the other way around would be a little less confusing :-).

Just my two bits.

(BTW, I'm using some software at work that has the REALLY annoying habit of placing dialogues which are triggered by the menu at the top-left of the screen at the bottom right of the screen! Drag, drag, drag. ARGHHH!)

2823. Sound Chip: What are the volume levels?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-20 23:41:29 UTC
From: warwick@cs.uq.oz.au
Message-ID: <9466@uqcspe.cs.uq.oz.au>
Source record: 43525

According to the Abacus Internals book, the volume levels on the Yamaha sound chip in the ST uses "logarithmically raised" volume levels.

I'd like to know exactly what the volume levels are, in order to calculate a better "magic table" for my sampled sound player. I've looked at the tables used in some programs, and they don't seem too accurate according to some of the calculations I've done - but I don't know how they came up with them.

If someone can find out what the "logarithmically raised volume levels" are, I can post the be-all-and-end-all set of "magic tables", so we can all benefit.

I tried a guess of sqrt(2)^V, and it seems pretty good - maybe even better than the tables I was using before.

With the program I've written, I can produce "magic tables" of varying characteristics - eg. one to play softer-recorded sounds at increased volume without first doing an information-losing scale-up. The Sun Sparc "ulaw" format could be trivially supported by this program too - it should give quite EXCELLENT reproduction of those sampled sounds - probably even better than is possible with the STe/TT DMA sound hardware.

All I need is the coefficient of the "logarithmically raised" volume levels.

2824. GNU C object file format (.o)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-21 00:38:17 UTC
From: rosenkra@convex.com
Message-ID: <1992Jul21.003817.25951@convex.com>
Source record: 43526

after grepping around my GNU C included directory, i could not find a
file describing the object file format (ie .o files). the st-out.h file
describes executables and their header. the .o magic number is 0x0107L.
there also appears to be at least 2 levels of indirection in the data
segment with initilized (global) data. i checked MiNT libs PL 19 and
std GNU C PL 71 and 73. ar.h does (of course) not help either. this
info is not normally found in many system's a.out.h file (eg convex
uses a format called SOFF which is documented in <convex/filehdr.h>
and <convex/scnhdr.h>).

i od'ed a few .o files and sort of figured out what they look like but
i was wondering if this is more formally documented. i suppose looking
at the src to ld would help and i will do that eventually. i also have
the GCC manual (at rev 1.31, the 200+ page thing). while it details RTL
i did not spot anyting on the .o format, leading me to believe it is not
too portable (obviously text segments will differ). i don't really want
to have to poke around gas src if i don't have to. and i don't believe
i have the gas src handy anyway, not, at least for the ST.

also is the .o format itself common to GNU C on other (non-atari) platforms?
is it called GOFF by any chance? 1/2 :-)

finally, is the .o format for gcc 2.x identical to that for 1.4 (gas 1.38)?
i would also suggest adding such header files as necessary to describe
this format if possible. normally this is not necessary for most applications
but i am toying with the idea of using .o files as a convenient way of
storing /usr/lib/term/tab* files for nroff (like some unix systems do).
the alternative is text (somewhat slower on startup but easier to maintain).

thanx...

2825. ICD and partition types : HELP please

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-21 01:32:26 UTC
From: dtarico@violet.ccit.arizona.edu
Message-ID: <1992Jul20.183226.1@violet.ccit.arizona.edu>
Source record: 43527
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

In the ICD hard disk formatter, it asks for partition types. The manual hints that type other than GEM and BGM are possible, but it says nothing about what the other options are. Does anybody know what types of partitions are allowable? I want to set up partitions (large ones) for DOS and Spectre. What types of partitions should I specify for these? Any info would be appreciated. Thanks.

P.S. large = >32 meg, i.e. GEM doesn't cut it. Spectre seems to work fine on a BGM partition, but DOS doesn't seem to like it. Is BGM acceptable for either of these operating systems, or will it cause problems?

>

NO!!!!!!

Do not do this! PLEASE! That is not a documented TOS variable. The only true way to read the joysticks is to intercept the IKBD vector specifically for them. Kbdvbase (XBIOS #34) returns a pointer to a table of addresses for each handler. Vector number 6 (counting from 0) is called by the IKBD handler whenever there is a joystick event. The handler is called with A0 and the longword on the stack pointing to the joystick packet in the form:-

HEADER($FE,$FF),JOY1,JOY2

While I'm at it, vector #4 is the mouse handler and a relative mouse packet looks like this:-

HEADER($F8-$FB - button status in bit 0 an 1), DX, DY

From: tony@microware.co.uk
Message-ID: <1079@mwuk.UUCP>
Source record: 43530
Cross-posted to: rec.radio.amateur.packet,comp.sys.atari.st.tech

Hi Folks,

I am looking for a recent version of KA9Q for the ST. I found one for
FTP on plains.nodak.edu, but it is dated somewhere in 1988.

I'm really looking for a NOS version rather than a NET version.

Any pointers gratefully received. Email preferred if possible.

Thanks in advance.

Tony.

From: anisko@usdtsg.DaytonOH.NCR.COM
Message-ID: <1068@usdtsg.DaytonOH.NCR.COM>
Source record: 43534

I have a question about MiNT. I downloaded Mint 0.93, and put MINT.PRG in my Auto folder. Unfortunately, then neither my UIS III or Warp 9 loads in (or are disabled, as they are loaded prior to Mint). Am I doing something wrong (AUTO order off maybe?). I can run UIS from the desktop to fix that part, but not Warp 9...

2831. DTP troubles

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-21 13:00:26 UTC
From: carl@syscon.rn.com
Message-ID: <1992Jul21.130026.7418@syscon.rn.com>
Source record: 43537

I could sure use help with two problems. My wife is using Timeworks DTP to do a little project. It won't print right on the NX2420. The GDOS printer driver is the Epson LQ, which should work. But it seems that lines of graphics data that are 512 bytes long don't get printed. You get space instead. But the data can be seen using the hex dump debug mode on the Star. Has anyone seen this? Is there a fix?

Part two is that I loaded up Timeworks on my Mega to try to print her project on my SLM804. Out of 5 tries, one printed the page. The rest packed the page into a 1/8 or 3/16 inch line at the top of the page. What did I do wrong? (I haven't read TFM - no time.)

2832. Memory Upgrade

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-21 16:55:10 UTC
From: raycole@matt.ksu.ksu.edu
Message-ID: <14hfheINN86f@matt.ksu.ksu.edu>
Source record: 43531

Yes, its another request for help with a memory upgrade. I have a 1040 STfm and am discovering that 1 Meg of memory just isn't enough. What I'm wondering is what upgrades are available that use simms and where could I get them, or how hard would it be to upgrade with out a over the counter kit. Any help would be greatly appreciated, especially since the last time I talked to the local Atari dealer he said that he'd performed a lot of upgrades but never had a call to do upgrades with simms. But then he's never tried to keep up with the real world. Thanks in advance.

Does anyone else get bombs between the time that the switch is turned off and when the computer is completely powered down? I notice on my STe that I get a brief glimpse of a few bombs almost every time I turn it off... It's certainly nothing to worry much about, but it does somewhat annoy me that there is some (presumably) unpredicted behavior going on in those last few microseconds.

[remainder deleted]

Don't worry. I am not going to FORCE anyone to use a program with a rebellious mouse, although you tempt me :-). If I could get GEM to cooperate, I would include this as an option you can ENABLE (rather than disable). This is rather mute, however, since the only suggestion I have received for moving the mouse is to use appl_tplay(), which I can't get to work at all. You need not loose any more sleep on this issue.

I had some spare time so I began to work on a FAQ for comp.sys.atari.st.tech
This is what I have come up with so far. I was unsure as to how far to
extend the scope of this, but sections can be added/deleted as appropriate.
All comments and contributions are most welcome, and since this is a first
draft, I take absolutely no responsibility for the inevidable errors in this.
(not that I would anyway!)

My email address is: mintha@geog.ubc.ca if you have problems with this then
you can try mailing to dorothy@presto.ig.com with some sort of note at the
start mentioning that this is for me (Jim Mintha)

(csas-FAQ refers to the comp.sys.atari.st FAQ)

Table of Contents:

0. Read the comp.sys.atari.st FAQ first
1. Programming

1) Language Alternatives
1) C Language
2) GFA Basic

2) Gnu Development System
1) Overview & requirements
2) What files are needed
3) Installation
4) Common Problems

3) Operating System Specifics
1) Where to get more info
2) UNIXMODE - what is it

2. MiNT
1) Overview
1) What is MiNT
2) What isn't MiNT (& what is MultiTOS)
3) What do you need to run MiNT

2) Installation
1) What Files are needed
2) Addition Files

4) MGR

3) Using MiNT
4) Programming with MiNT
5) Other Problems

3. Hardware Mods
1) Memory Upgrades
2) Overscan
3) Accelerators

And this is what I have so far in the way of answers/contents

1. Programming.

1.1.0) Language Alternatives

(From csas-FAQ) Languages available for the Atari ST:

68000 assembly, abc, APL, awk, Basic, C, C++, Elan, Fortran,
Forth, Icon, Lisp, Modula2, OPS5, perl, Prolog, Scheme,
Smalltalk, Xlisp, Xprolog, Xscheme

1.1.1) C Language

'C' is probably the most widely used language available on the
atari ST (For good or bad - no flames please) There are a number of C
packages available, this is a non-exhaustive list of them, with
their relative (de)merits. (+, and -'s)

Pure C (formerly Turbo C)

+ Full integrated environment
+ Fast and produces Good Code
+ Ansi compatible
+ Has integrated source debugger

- Documentation is still in German

Laser C

(Haven't tried it)

Gnu C (et. al.)

+ Available for free
+ Produces good code
+ Source Debugger
+ Ansi compatible
+ Source Code available

- Requires at least 2.5 meg and a bunch hard drive space
- Not that fast

Sozobon C

+ Available for free
+ Source code available
+ Small (no hard drive needed/ 1Mb machine okay)

- Not ansi compatible
- Not that fast

Heat & Serve C

(someone explain what the difference here is?)

1.1.2) GFA Basic

(haven't used it)

1.2.1) Gnu Development System

The GNU package (GNU stands for Gnu's Not Unix) is a suite of program that provide a complete development system. It is available for quite a number of computers. (for more info on the GNU project check out the newsgroup gnu.misc.discuss, or FTP information files on prep.ai.mit.edu (pub/gnu/...)) The majority of the program have been port to the ST thanks to the efforts of a number of people (insert names of people who have done this - Bammi, etc.) (see csas-FAQ :GNU:)

System Requirements:

The Gnu C compiler requires at least 2.5 meg to compile anything more than a Hello, World! program. The bigger the program the more memory (especially with optimization)

1.2.2) What Files are Needed

There are quite a number of files needed to get GNU up and running these are the files I needed from atari.archive:

Directories are at atari.archive in atari/gnustuff/tos (=~)

gcc21b02.zoo (~gcc/) Binaries for C compiler
gccdoc.zoo (~gcc/) Documentation for GCC
libolb80.zoo (~gnulib/) Gnu Library files (binaries)
gmlibo23.zoo (~gemlib/) Gem library files (binaries)
includ80.zoo (~include/) Include files
pmlolb18.zoo (~pmathlib/) Math library files (binaries)
utlbin27.zoo (~util/) Binaries of other program (gnu-ld gnu-as etc.)
gplibo07.zoo (~g++/) G++ libraries (binaries) (for C++)
gpincl07.zoo (~g++/) G++ include files (for C++)
crt.zoo (atari/new)* startup files crt0.o and gcrt0.o (in new directory until they are moved to the correct spot.)

Notes:

The above is for version 2.1 of the compiler. There are also binaries for version 1.4, which also works well, and is a bit smaller.

Source files for all of the above can be found in the same directories as the binaries.

The compiler (gcc) will compile both C, and C++ code (ver. 2.1 - 1.4 has separate programs gcc and g++)

1.2.3) Installation

How you install the files on your hard drive is somewhat dependent on how you organize the layout of your hard drive, whether you are using UNIXMODE (see section 1.3.2) and the phase of the moon.

The is the basic tree on my drive D:

```
d:\gnu\
bin\
lib\
include\
```

Throw all the executables in bin, the library files in lib, and the include files in include/gcc or include/g++

You will also need to set some environment variables. How you do this will depend on what shell you are using.

```
GNUINC is a comma separated list of directories where you put the
include files for the library.
GXXINC is a comma separated list of directories where you pu the
include files for the g++ library
GCCEXEC is the directory where the binary executables gcc-cc1.ttp
gcc-cpp.ttp, gcc-ld.ttp, etc. are located (must add the gcc- at
the end as gcc will look for $GCCEXEC + cc1.ttp etc.
TEMP is a directory where the compiler can write temporary files
(a ramdisk is good here)

setenv GNUINC 'd:\gnu\include\gcc'
setenv GNULIB 'd:\gnu\lib'
setenv GCCEXEC 'd:\gnu\bin\gcc-'
setenv GXXINC 'd:\gnu\include\g++'
setenv TEMP 'd:\tmp'
```

After all this you should be able to type

gcc -o hello hello.c (provided hello.c exists :)

Notes:

If you are using gulam you should add
set env_style mw
to your gulam.g files

If you are using MiNT then you can use /dev/d instead of d:

You need to add the path to gcc.ttp to you path variable

If things don't work, try gcc -v which will tell you exactly what it is doing

For C++ you need to add -lg++ for example:
gcc -o hello hello.cc -lg++

1.2.4) Common Problems

Prob: Upon linking you get errors with references to a symbol _splitmem_
and other errors.
Answer: Get the current version of crt0.o and gcrt0.o (If you can't
find them, you can get the source to the gnu libraries, and compile
crt0.c (gcc -c crt0.c) to get crt0.o)

1.3) Operating System Specifics

1.3.1) Where to find the information.

The best way to get a lot of information concerning the internals of
the operating system is to become a register developer. You will then
get a whole bunch of documentation.

Alternatively the following files are available; (somewhere)

"Hitchhikers guide to the Bios" - describes all the bios, and xbios
calls. As well as atari's VT52 emulation, and miscellaneous other
interesting stuff. Can be found...??

"Gemdos Guide" - describes the gemdos calls

???

1.3.2) UNIXMODE

UNIXMODE is a method of providing access to longer files names under
TOS. In a nutshell it maps longer names to TOS's 8.3 length. It
keeps the mappings in a file called .dir in the same directory as the
file. UNIXMODE is not a program in itself, but rather just an
environment variable. If a program supports UNIXMODE then it will
allow you to use the longer file names, other programs will just use
the shorter TOS ones.

Further documentation on the use of UNIXMODE can by found in
UNIXMODE.doc which is located somewhere on atari.archive

2. MiNT

2.1.1) What is MiNT?

From the mint documentation:

...

mint section still being worked on

3. Hardware Modifications

I haven't done many hardware mods on my atari, so any info for this
section would be appreciated. Commercial add-ons belong in csas-FAQ
rather than here. This more homebrew kind of stuff.

Contributors:

Still to be done.

2840. Problems with (MiNT-)BASH and GNU configure scripts

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-22 10:34:20 UTC
From: jensk@hpbbrd.bbn.hp.com
Message-ID: <9130023@hpbbrd.bbn.hp.com>
Source record: 43462

Has anybody used BASH (the MiNT-aware version) to run one of the configuration scripts supplied for the recent versions of various GNU utilities (fileutils, grep, ...) ?
Whatever I try, BASH tells me that there are syntax errors in the script.
If I run the script via 'bash configure', I get one specific error; if I run it from BASH by '. configure' or 'source configure', I get a different one.
Needless to say, if I isolate part of the script and run BASH on it, it works just fine.

Has anybody seen this? Is it a bug in BASH? Am I doing something wrong?

Thanks in advance,

Jens.

(Going to try KSH now ...)

Speak for yourself. The practice is commonplace on X11 and, frankly, is
very useful when you become acustomed to it.

Hello,

Just updated "gemview.prg" version 1.1 to version 1.1m and have a problem.
The old version worked extreamly well in a 256 color mode on the crazy-dots
video card. Generated great pictures on a 21" Eizo grey scale monitor.

The new version only works in 1, 4, 16 colors under crazy-dots, if
I am in a 256 color mode, I get a window that should have the picture in
it, but really contains some scrambled pixels. Also in the 256 color mode
version 1.1m seems to ocassionly crsh the system.

Is there a bug in the version, or am I being stupid and not seeting a flag
in a setup menu or something?

cheers,
scott kolodzieski

2843. Problems hooking up a SCSI drive

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-22 15:41:19 UTC
From: sslee@micromed.com
Message-ID: <kFLBoB2w165w@micromed.com>
Source record: 43448

I recently purchased a Micropolis 1375 (150 MB) hard drive. I currently have the old ICD Host Adapter connected to a generic 20MB drive and it runs fine.
Problem: After removing the old 20MB drive and connecting it with the new drive, it just doesn't seem to work. The drive starts up and kicks in, but the ICD software (version 5.x.x) can't seem to find any SCSI devices. I've seen the drive working on a PC as device ID 0, LUN 0, so I know it works. I've already checked to ensure the SCSI controller has terminating resistors.

Any help would be appreciated,
Steven Lee

I had the same problem, too. It can be solved by loading all those
programs from the mint.cnf file. But I think mint093 has a bug so you
can't do this, but mint094 works fine. At least on my TT.

I recently installed a 4meg upgrade into my 1040ST. It's a tech-
specialties board version 1.1 for a 1040 version 1 motherboard. Well, I
have a 1040 version 3 motherboard. Anyways, after rebuilding the data and
address lines, the only way to get my computer to boot up was to leave power
to the old memory chips. I left the old memory chips in place, but had
dissconnected all the data, address, and control lines, but they still need
power for my computer to boot????? Also, when I turn on my computer, I
have to press the reset button about five times before the system boots up,
once booted, it works fine and passes all memory checks as long as the system
is on. Go figure. Any ideas why?
Thanks,
Jonathan

From: chu@acsu.buffalo.edu
Message-ID: <Brt58v.CAw@acsu.buffalo.edu>
Source record: 43450

Hi,

I've been using the make that comes with HSC with gcc (mostly because I don't have another make). But something really interesting happens. If I run it off the desktop everything is fine (except the desktop doesn't do redirection, which means I can't run the makefile in question). However, if I run it under tcsh or mintshel, the programs that make calls complain that they don't get any command line arguments.

I guess that this has something to do to the protocol for passing command line arguments (as in tcsh and mintshel uses ARGV but the HSC make doesn't(?)). In any case, is there anything I can do about this other than get a new make?

If getting a new make is the only answer, can someone tell me where a good one is? I've already checked atari.archive. GNUmake 3.62 gives an out of memory error when ever I try to run it (even though I have 3.5 Meg free before trying!) I don't think I had much luck with GNUmake 3.60 either.

What does everyone else use? I can't be the only person who wants to use make under tcsh or mintshel!!!

Please reply via e-mail. I'll post a summary.

Source record: 43452

In article <mfg.711660187@gmd.de> mfg@gmd.de (Martin Gergeleit) writes:
>You are right with the analysis of my problem. But I think there is another
>solution to it. With MiNTs call Fcntl(..., F_SETFD) you can force a file
>handle to be inherited to Pexeced childs. If the pty now is created at DAs boot-
>time, it will be inherited to all GEM programs (and their DAs).

But all processes 'loose' one file-handle... Shure it will work, but
the method with a second 'sub-process' does not have this restriction.

A second problem occurs with the memory, the DA allocats while another GEM
pogram is running. If the process terminates, the memory is freed. This

And the last big problem that you will meet (when continuing in the DA/xterm-
quest...) is that a process that was started under the desktop in your xterm
clone is in the sleeping state after you start a new GEM process ;-)

>These two problems should be handled by starting the TTP with the mode 100 of
>MiNTs Pexec, I think. (correct me if I'm wrong).

This did not work for me... If you spawned the process while in the desktop,
the new processes are childs of the desktop. When starting a new GEM-process,
the desktop was sleeping (it? used pexec(0)...) an so did his children.
(I am not 100% shure of this.. In my DA this migt have happened because the
output pipe of the paralell process was full, because the DA looked after
a 'different' file-handle to read from...)

Greetings, Karsten

2854. Re: Problems hooking up a SCSI drive

Source record: 43453

Hi,

You might want to check that parity is enabled (or is it disabled)
as that can really mess you up. Also, does the ICD utilities say that it has
found the host adapter? There should be a utility to scan the SCSI bus, and if
it doesn't find the clock (usually device 6) then it is more likely that the
problem is with the Host Adapter. Check the power to the Adapter, and the
SCSI cables going in and out. Finally, check that you have plugged the ACSI
cable into the right ACSI connector if your Host Adapter has more that one
(it should be labled IN).

Good luck!

If it was running on a PC, chances are that the jumper is set for
Parity Enabled, and I found (by trial and error) that the ST likes to
have it disabled.

> When run under mintshell or tcsh it doesn't pass arguments correctly.

The fix will be released Real Soon...the new version of STMAKE (now in testing) uses the ARGV standard to pass args, and that should fix your problem. (All the new compiler pieces use ARGV now, so you can link programs that have a hundred modules without messing around with linker command files and stuff.)

Actually, since STMAKE is packaged separately as well as bundled with HSC, and there've been no bug reports, I could probably release it now, before the rest of HSC v1.40.

2) Freely available Gnu Development System **** (many people haven't heard of "Gnu")

>2. MiNT
2. MiNT Multitasking Environment **** (at least give a clue)

>Gnu C (et. al.)

>- Not that fast ***** HEY! Don't scare people away from it!
- Not that fast to compile (but generates fast code)

>1.2.1) Gnu Development System

>The Gnu C compiler requires at least 2.5 meg to compile anything more
>than a Hello, World! program. The bigger the program the more memory
>(especially with optimization)

This isn't exactly true. You need 2.5 meg to work, and you'll always
have to keep separate modules small, but 4 meg will let you do anything
at all.

>Notes:

>The above is for version 2.1 of the compiler. There are also binaries
>for version 1.4, which also works well, and is a bit smaller.

In fact, 1.4 works quite comfortably with 2.5 meg.

>The compiler (gcc) will compile both C, and C++ code (ver. 2.1 - 1.4
>has separate programs gcc and g++)

- Also supports Object C
(not that I've used Object C)

Now the info on C++ ...

C++, being based on C, interfaces with all C code - which includes the
operating system of the Atari.

Packages available:

GNU C++ (g++)

Comes as part of the GNU C compiler.

Cormeau C++

No idea, but it is available.

There is a company called Sam's that publishes all sorts of schematics.
They have been around for years, and every radio and television repair
shop has dozens of their things. The publish a schematic for the ST.

Source record: 43490

I had the exact same problem with my mouse. I thought it was a broken trace
on the PCB, or (even worse) a broken cable. However, after some looking
at the PCB with a magnifying glass, I found that one of the pins of the
little SMD chip had come off because it was badly soldered. I resoldered it,
and since then the mouse has been working without problems.

Good luck,

Jens.

> to work right.

NO it is NOT (obviously) incorrect! gcc-cc1plus.ttp (or
gcc-cc1p.ttp if you are UNIXMODE impaired) is the correct name for
the g++ compiler for version gcc-2.X where X>= 0. in gcc 1.X the
compiler was known as gcc-cc1+.ttp, and was driven by g++.ttp. In
version 2.X g++.ttp does not exist, and the common driver (gcc.ttp)
invokes the correct passes based on the filename extension.

Having finally found a ramdisk (Mdisk from a.a) that can live in TT-RAM,
it now turns out that it is incompatible with MiNT. Anybody go any ideas?
Is there another ramdisk that might work, or perhaps can one use MiNT
to create a ramdisk?

You can make a Spectre partition as large as you want, preformat it as BGM
and than convert it into HFS. This does not belong to your GEM driver
software, e.g. if you're using ICD or AHDI or what else. The format identifier
of the Spectre partition then is "OOP".
Concerning DOS partitions, my first idea is the DOS version you are
using. Be sure to use 4.01 or later, I remember there were problems
formatting large partitions with former DOS versions.

I think some programs implement this. One thing you might try is a
"soft clipping" table for overdrive effects.

I doubt you'll get better quality than the DMA chip. For one thing the Yamaha
chip is pretty noisy and anyway even an 8bit table is far from perfect.

BTW has anyone managed to get >9 bits of sound out of the DMA chip by fiddling
with the volume control chip in real time (an amiga coding trick) or is
the microwire bus to slow?

Steven

2867. Does the STe REALLY have 8 channel DMA sound ?!

2869. Re: Sound Chip: What are the volume levels?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-23 12:22:40 UTC
From: eye@lesti.hut.fi
Message-ID: <EYE.92Jul23122240@lesti.hut.fi>
Source record: 43466

According to the Abacus Internals book, the volume levels on the Yamaha sound chip in the ST uses "logarithmically raised" volume levels.

I'd like to know exactly what the volume levels are, in order to calculate a better "magic table" for my sampled sound player. I've looked at the tables used in some programs, and they don't seem too accurate according to some of the calculations I've done - but I don't know how they came up with them.

I have also noticed the same problem, I looked through many sample tables I got. After several weeks, I finally came up with a solution, which seems right (please don't flame me if I am wrong!). The accurate volume levels seem to be:

Sound chip Volume Real Volume (down from max.)

15 -0 dB
14 -3 dB
13 -6 dB
12 -9 dB
11 -12 dB
10 -15 dB
9 -18 dB
8 -21 dB
7 -24 dB
6 -27 dB
5 -30 dB
4 -33 dB
3 -36 dB
2 -39 dB
1 -42 dB
0 -45 dB

So a change of 1 in sound chip volume value will change the real volume by 3 desibels. And desibels of course are calculated like this:

dB=10*lg(I/10^-12 W/m^2)

where lg is 10-based logarithm and I is intensity of sound.

With one sound channel you can achieve maximum of 45dB dynamics, but sound quality will be poor. With combined 3 channels you will get max. 49.8 dB dynamics (10*lg(3*10^4.5=49.7712...). Most sample players use all the sound channels to get more accurate simulation of the 256 8bit-sample values. I don't know how the freq. values (in sound chip register 0-5) affect the volume, but I guess with the use of them one could achieve even better dynamics. (Normally sample players on ST, set the frequency-registers to zero and set all sound channel off -> mixer register).

If someone can find out what the "logarithmically raised volume levels" are, I can post the be-all-and-end-all set of "magic tables", so we can all benefit.

Yes, post the table! It would be nice if you would also calculate a table for 1 sound channel samples (eg. many ST-musicians use only one channel to produce digi-drum sounds).

I tried a guess of sqrt(2)^V, and it seems pretty good - maybe even better than the tables I was using before.

With the program I've written, I can produce "magic tables" of varying characteristics - eg. one to play softer-recorded sounds at increased volume without first doing an information-losing scale-up. The Sun Sparc "ulaw" format could be trivially supported by this program too - it should give quite EXCELLENT reproduction of those sampled sounds - probably even better than is possible with the STe/TT DMA sound hardware.

All I need is the coefficient of the "logarithmically raised" volume levels.

When you calculate the "magic" table, try to get the the most silent sample values correct, human ear becomes more inaccurate with louder values and it's not so important to get them correct.

2872. TT SCSI woes again...

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-23 16:04:54 UTC
From: vspicer@ccu.umanitoba.ca
Message-ID: <1992Jul23.160454.12859@ccu.umanitoba.ca>
Source record: 43472

is anyone out there using Klaus Pedersen's SCSI driver code for the TT? i've modified it slightly to work under Lattice C 5.5 but it's giving me a hard time.

the assembly routine that selects the SCSI device always times out, no matter how long a timeout period i give it. about a year ago i wrote my own code to drive the SCSI bus in C, but it doesn't do DMA transfer properly and needs to handshake data across. when we found Klaus' code we were quite pleased.

the thing that absoulutely killed the speed on my C routines was the device selection. it had to waste a lot of time just sitting in delay loops. Klaus' code is much more elegant about this, but it also appears to not work on our machine.

any help or comments would be appreciated
thanks in advance
vic spicer

2874. Is page flipping safe, and I need to know about syncing

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-23 17:08:09 UTC
From: chu@acsu.buffalo.edu
Message-ID: <Bruq9M.FI7@acsu.buffalo.edu>
Source record: 43473

Is it ok to use Setscreen to do double buffered animation (i.e., draw on one buffer while the other is being displayed and switch. I don't know if I've used the right term for this). By that I mean, does it work on all nominally ST compatible computers, including those with video cards? (Of course, I'd also pay attention to what GEM tells me when I start up so that I reserve enough memory for each screen.)

Also, a little while back, someone (Dave Baggett??) was talking about how one should sync one's game to update the screen every n vblanks (where n depends on how much is happening in the program), which will among other things, insure that the game plays at the same speed across variants of ST-type computers. Unfortunately, I wasn't paying attention at the time. How do I do this?

After a hiatus, I've decided I'm going to return to trying to program the ST again, so I want to make sure whatever I do will work on as many ST-type computers (i.e., STe, Mega STe, TT, Falcon, unusual configurations of those etc.) as possible (actually, working on all of them would be preferable).

Thanks!

john

The Setscreen and Vsync (X)Bios calls work fine for double buffering (aka "page flipping"). There are some subtleties but for most practical purposes you'll get good results using these calls and your code will work with all versions of TOS (including, in theory, those that are forthcoming). You want to call Setscreen first and then Vsync. It doesn't work to call Vsync and then Setscreen. Read the Setscreen docs for an explanation of why.

Video cards that have drivers that steal the (X)bios calls should also work. I don't know how this translates in the real world though, since I don't have a special video card.

>Also, a little while back, someone (Dave Baggett??) was talking about
>how one should sync one's game to update the screen every n vblanks

>among other things, insure that the game plays at the same speed
>across variants of ST-type computers. Unfortunately, I wasn't paying
>attention at the time. How do I do this?

The scenario: You write a game with sprites, sampled sounds, and maybe a scrolling window. Chances are your game isn't going to complete all of its processing for each "game turn" within 1/60th of second on a stock 8Mhz ST. This means that it will take 2 or more vertical retrace periods to update the screen. This isn't a problem in terms of smoothness; most commercial games run at 2, 3, or 4 vertical retraces per game turn and they look fine.

The problem: when you run your game on a faster machine (e.g., a Dave Small 50Mhz accelerated '030 ST) your game might actually do all its work within a single vertical retrace period (or at least in fewer retrace periods than it would on a stock ST). The result is that your game runs way too fast.

The solution:

Instead of syncing to every single vertical blank, write a short routine that checks the frclock system global and doesn't return until at least n vertical blanks have passed. That way if you're running on a 100 MIPS supercharged ST your game will finish all its processing for a particular game turn in the blink of an eye and then just sit there waiting until the given number of vblanks have passed. If it seems criminal to waste so many cycles I suppose you could

use the extra time to make the enemies more intelligent if you were careful about it. Or compute primes, for that matter. :)

You need to tune your game to the minimum number of vertical retrace periods that the slowest supported machine requires to complete all the processing for a game turn. You can do this scientifically by keeping track of how many vertical blanks are happening per game turn on average at the most "busy" point in the game, or you can just play it by ear and pick a high value (6, for example) and then bump it down stepwise until you see no difference in gameplay from one step to the next.

A concrete example: HacMan II uses the value 4 here, largely because the ghosts' "thinking" algorithms are quite slow (relative to the drawing speeds, at least). I think Blox runs with 3 vsyncs per game turn. In the case of Blox the 11kHz samples slow down a stock ST quite a bit. But even if you use DMA stereo sound (which requires no CPU cycles) the game will still run 3 vsyncs per game turn; hence game play is totally unaffected by either your choice of CPU or sound D/A device.

The frclock system global is documented by Atari and guaranteed not to change, so you should be safe using it.

Dave Baggett

"Double-buffering" or "page-flipping." And, yep, Setscreen works for
all standard ST and TT resolutions (though they are different sizes,
you need to check the resolution and use bigger buffers on the TT).
I don't know about video cards, but I expect you'd have to use VDI
calls for them...

>Also, a little while back, someone (Dave Baggett??) was talking about
>how one should sync one's game to update the screen every n vblanks

First you decide the maximum number of 1/60 second intervals it will
take to draw your most complex screen (say 4). Then you write your
drawing routine so it keep track of how many jiffies have gone by
since it started to re-draw the screen (between 0 and 4, depending on
the complexity of the screen). Then you just wait out the remainder.
If a simple screen takes 1 jiffy to draw, you wait for three. If a
complex screen takes 3 jiffies to draw, you wait for one. And the
game runs at the same speed (4 jiffies per refresh) no matter how
complex it gets.

That's the way to do it.

Source record: 43476

Someone wrote about upgrading their ST from a 68k to an '030 a couple of posts back. I can think of several problems right off the bat: 1) you are talking about putting a 32bit chip into a 16bit bus, so you would have to do some intelligent memory fetching to make it as trasnparent as possible (which means that speed just went down by 1/2). 2) you won't have any support for enabling/disabling the on-board cache (yes, people still write cache-insensitive code so you gotta be able to turn off all 512bytes of cache). 3) Unless you have TOS1.6 or higher, the TOS will be incompatible. All in all, unless you have lots of time, and a great set of designing skills, don't bother.

However, this turn of thought makes one wonder about something that on the surface seems much better:

Assuming you make a small logic board to enable pin compatibility, can the '030 in the TT be replaced with the '040 without much of a major hassle (ie: is it more complicated than stealing the signals from the '030 (and disabling it) and routing them to the '040?) As far as I know, the only major difference (hardware wise) is the larger cache and the bus-snooping logic (which wont make much of a difference if you don't plan on putting more than one '040 in it - Hmmm maybe two...:). Can anyone think of a good reason for shooting this down? Or should we all be getting out our bread boards (ha! more like etched boards:) and turbocharging our TTs?

Food for thought...

-Mike

For most practical purposes you do get good results with this.

BUT: the disadvantage is that you don't have precision page flipping. It
just may happen that on screen1 you are done drawing in 2 screens and flip
then, while on screen2 you need 3 screens. The net effect of that would
be that if your flip rate is 4 that screen 1 will be displayed 5 VBIs, where
screen2 will be displayed only for 3 VBIs. If your game nears completion
and you are not 100% satisfied with the animation I'd suggest that you
use the VBL directly to flip pages (you can use Setscreen()) there too.
Until then Setscreen() + Vsync() + frclock will suffice.

Source record: 43478

My sm124 montior has died on me. I still have power (the speaker still works) but the screen is completely dark. Any ideas if this is fixable?

For a few days before it died the monitor was acting strangely. The image would swim and change size for a few seconds and then go back to normal.

Thanks,

From: dtarico@violet.ccit.arizona.edu
Message-ID: <1992Jul23.175236.1@violet.ccit.arizona.edu>
Source record: 43481

I connected a 1.4 meg floppy to my Mega ST and installed a switch to
switch the WD1772 between 8 and 16 mHz. It works fine, except that
after I switch clock speeds a couple times, the dirves start giving trouble.
It seems like the 1772 is locking up or something, as everything is fine
again after a reset. Does anybody know how to make the switching more stable?

I designed a box for a company called Kiztoy Developments out here (Oz)
which gives a total of 3 midi in's (with merge), 6 midi outs (separate),
SMPTE in and out with Creator/Notator (including the Atari midi in/out
port) and 3 midi ins, 3 midi outs, SMPTE with Cubase. I think he sells it
for around A$600. All I can say is that only a small part of it was trivial,
the rest took a little thought.

Some months ago replacing the '030 by an '040 was discussed in the
m68k-newsgroup. The result was that it's nearly impossible to do so because
there are some major obstacles to it. Don't ask me what the problems are in
detail because I don't know. But there was a general consensus that using an
'040 instead of an '030 is not as easy as some may think.

Nat! is right and has pointed out the "subtlety" I alluded to. In practice it doesn't make a whole lot of difference since you don't often find a game that goes 3, 2, 3, 2, 3, 2 consistently enough to look jerky; the priciple of locality tends to hold in game timing as well as it does in the rest of the computer world, and so you usually find that your game will run something more along the lines of 4, 4, 4, 4, 4, 4, 4, 3, 3, 3, 3, 3, 3, 4, 4, 4, 4, 4, 4, ...

It isn't so much a problem with the vsync counting code as with Setscreen. Remember that you don't wait _exactly_ n vertical retraces each game turn; you wait long enough to ensure that _at least_ n vertical retraces have happened since the last game turn. Assuming n is 4, your example would work out as follows:

frclock screen frames req. condition to wait on #frames to wait

1000 1 2 frclock >= 1004 1004-1002 = 2
1004 2 3 frclock >= 1008 1008-1007 = 1
1008 1 2 frclock >= 1012 1012-1010 = 2

screen one is visible through the period from 1004 to 1008, during the time screen two is being computed and drawn to, which includes the 1-frame wait starting at 1007.

screen two is visible through the period from 1008 to 1012, during the time screen 1 is being being computed and drawn to, which includes the 2-frame wait starting at 1010.

The vsyncing algorithm I described simply adapts itself dynamically to the CPU requirements of the game.

The problem is that Setscreen sets the screen as soon as the *next* vblank comes around. Nat!'s right in thinking that you need to wait until the end of your ~n vertical retrace waits to set the actual screen pointer. One way around this is to call the adaptive vsync routine with n-1, then call Setscreen, and then call Vsync(). Then you're still OK with respect to the cross-machine compatibilty but your timing is exact.

>If your game nears completion and you are not 100% satisfied with the >animation I'd suggest that you use the VBL directly to flip pages (you >can use Setscreen()) there too. Until then Setscreen() + Vsync() + >frclock will suffice.

Calling Setscreen from an interupt seems very dodgy to me. It may work now, but I wouldn't count on it working forever.

Source record: 43487

First, this is a test post. Hopefully the dad-blamed NewsReader here will really send it. Who knows, Pigs may Fly, too.

Also, if this gets through, Ian Lepore, your messages get to me, but nyx doesn't seem to be willing to admit to the outside world that you exist.

Bye,

Mike.

2890. Re: Test post / Message for Ian Lepore

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-25 00:55:35 UTC
From: ilepore@nyx.cs.du.edu
Message-ID: <1992Jul25.005535.6901@mnemosyne.cs.du.edu>
Source record: 43489

Nyx has gone through recent hardware and software upgrades, and the mail system in particular wasn't working well. It seems to be fixed now, and it should be possible to reach me at ilepore@nyx.cs.du.edu; if that fails, you can try ilepore@newnyx.cs.du.edu.

The password file here is getting nuked on a semi-regular basis, so some mail may get bounced back as "unknown user", but if you resend it, it should get through the second time.

I've been getting mail from the outside world yesterday and today, so it does seem to be fixed now.

2891. Help!!! Minix ignores 2nd HD (ST)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-25 07:33:28 UTC
From: adamd@rhi.hi.is
Message-ID: <5152@krafla.rhi.hi.is>
Source record: 43391
Cross-posted to: comp.sys.atari.st.tech,comp.os.minix

I added a 2nd hard disk to my 1988 Supra hostadaptor, and it works fine under TOS. I set the partitions to type MIX, recompiled the minix kernel for 2 hard disks and added the device nodes for the new partitions. Minix refuses to recognise the extra diskspace on all counts. The disk LED does not light.

I have the new disk on scsi id 1, lun 0. What I suspect is that minix is looking for the 2nd disk on scsi id 0, lun 1. As far as I can see there is no way to set the disk to be at lun 1 with this hardware (it is an embedded SCSI disk). Has anybody got such a setup to work? or do I have to change the hardware first? Minix version is 1.5.10.4

1st disk: scsi0,lun0 partitions C: D: are GEM, E: F: are MIX
2nd disk: scsi1,lun0 partitions G: H: are MIX

Maybe I should try #define NR_HD_DRIVES 3, but this is of course stupid to access the second disk as if it were the third one. All sensible approaches have failed, so its time to be silly. Any other suggestions?

>access the second disk as if it were the third one.

I guessed right. However there is another problem: Now the disk is working
but I keep getting "DMA interrupt discarded" warnings whenever the 2nd disk
is accessed. This is ST Minix 1.5.10.4 with OLDSUPRA defined so that the
driver interacts correctly with the early type Supra hostadaptor. I could just
remove the warning text, but would prefer to mend the winchester driver so that
it does not suffer from spurious DMA interrupts. Has anyone already done this?
Suggestions about why this is happening, and only on the 3rd (actually 2nd)
disk??

2893. Numerous ST/TOS questions

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-25 14:57:59 UTC
From: ratlifc@marcus.its.rpi.edu
Message-ID: <+bwxx1@rpi.edu>
Source record: 43393

Hi all,

I've had an ST for about six months now. Its an old jobber with a tweety board and 2.5MB of RAM. I'm also running a version of TOS which was most recently copyrighted in 1987. I'd like to get more into this machine, however, I need a little advice from the old hands.

First, what is a good company to go to for Atari ST software, and who is good for hardware. I'm looking for the new edition of the operating system, a hard drive, and possible other extensions.
Next, I would like some documentation on the internals of the machine and its OS [this is why I'm posting to tech]. I'd like a full ins-and-outs of the hardware and how it compares with similar systems. Is it SCSI? Can you ethernet it? What is that catridge slot on the side for? These are the kind of questions I need answered.
Also, I've wondered who does tech support for ancient STs, for whom the warranty expired long ago.
In addition what are the magazines, and where can I send for an issue and subscription information.

Thanks muchly to any who answer,
Christian

PS. please respond via email <ratlifc@rpi.edu> and I'll summarize to the net if anyone seems to care.

Yes, because that's the id a second harddisk at SH20[45] gets.

But it is the right way. Your physical second disk is the logical 3rd.
Also you can see in /usr/include/minix/config.h:

~ /* define the number of hard disk drives on your system */
~ /* (assuming 2 drives/controller) */
~ #define NR_DRIVES 3 /* typically 0 or 1 */

> All sensible approaches
> have failed, so its time to be silly. Any other suggestions?

The above define works for me.

The main problem is that the bus handshaking has totally changed with teh
'040. On the 680[0123]0 the CPU has the bus by defaults and gives it up to
peripherals. On the 68040 the bus is "free" by default and is only acquired
by the CPU when necessary.

The other problem on course would be adding the '040 FP software to the
system :-) and hoping that TOS initialises the PMMU in the chip in the
correct way (the '040 only has a sub-set of the instructions for this that
the '030 has).

2897. ANSWER -> Using Joysticks

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-27 11:58:54 UTC
From: tony@microware.co.uk
Message-ID: <1143@mwuk.UUCP>
Source record: 43399
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hi Folks,

Recently I have seen a number of postings asking for details about using the joysticks on the ST. This posting attempts to provide some help.

I never saw it properly documented, so about 4 years ago, using information from the old Abacus/DataBecker internals book, I set about investigating the Keyboard vector routines, using a packet handler which I could patch into the vectors I wanted to investigate. The C program I used is given below. As written, it hooks into the status and joystick vectors. For just the joystick information, it is not necessary to use the status vector. Obviously, the program could be cut down to just bare bones for joystick handling, but I thought the complete thing might be of interest.

It was compiled using Lattice C 3.0.4. UBYTE is just a typedef of unsigned char. You won't need <portab.h> if you define this by hand. cprintf() is just printf() directly to the console. The include file <fctype.h> is just a variant of <ctype.h>, which itself would do fine.

It should be compiled to a .TOS executable.

```
------------------------------------------------------------------------
#include <portab.h>
#include <osbind.h>
#include <fctype.h>

typedef struct {
void (*midivec)();
void (*vkbderr)();
void (*vmiderr)();
void (*statvec)();
void (*mousevec)();
void (*clockvec)();
void (*joyvec)();
void (*midisys)();
void (*ikbdsys)();
} KBVEC;

UBYTE joy0,joy1;
UBYTE list[10];
int got=FALSE;

void dopkt(packet)
UBYTE packet[];
{
```

```
register int i;

for(i=0;i<10;i++)
list[i]=packet[i];
got=TRUE;

if (packet[0]>=0xFE) {
joy0=packet[1];
joy1=packet[2];
}
}

void main()
{
KBVEC *p,save;
UBYTE old0,old1;
char buf[128];
int cmd;
char c;

p = (KBVEC *)Kbdvbase();
save.joyvec = p->joyvec;
p->joyvec = dopkt;
save.statvec = p->statvec;
p->statvec = dopkt;

Ikbdws(0,"\x12"); /* Turn mouse off */

old0=old1=0xFF;
cmd = 0;

for(;;) {

if (Cconis()) {
c=toupper((short)Crawcin());
if (c=='\x03') {
Ikbdws(0,"\x08"); /* Restore mouse operation */
p->joyvec = save.joyvec;
p->statvec = save.statvec;
Pterm0();
}
else if (c=='\r') {
buf[0]=cmd;
Ikbdws(0,buf);
cmd = 0;
}
else if (c>='0' && c<='9') {
cmd = ((cmd & 0xF) << 4) | (c-'0');
cprintf("cmd = %X\r\n",cmd);
}
else if (c>='A' && c<='F') {
cmd = ((cmd & 0xF) << 4) | (c-'A'+10);
cprintf("cmd = %X\r\n",cmd);
```

```
}
}

if (got) {
cprintf("Packet = %02X %02X %02X %02X %02X %02X %02X %02X %02X %02X\r\n",
list[0],list[1],list[2],list[3],list[4],
list[5],list[6],list[7],list[8],list[9]);
got=FALSE;
}

if (old0 != joy0) {
old0 = joy0;
cprintf("Joy0 = %02X\r\n",old0);
}

if (old1 != joy1) {
old1 = joy1;
cprintf("Joy1 = %02X\r\n",old1);
}
}
}
```

Armed with the information gleaned by this program, it was possible to write assembler routines to setup, use and unsetup the joystick. JOYINI and JOYEND should be callable from ASM or C, and the global variables JOY0 and JOY1 will be updated automatically whenever a joystick state changes.

I can't remember what bit means what, but that is easily determined by trial and error.

```
;
JOYINI MOVEM.L A0-A1/D0,-(SP) ; Save registers
MOVE.W #34,-(SP) ; Kbdvbase()
TRAP #14 ; Xbios
LEA 2(SP),SP ; Better than ADDQ, as it
; doesn't set any flags.
; Now D0 points to the table of longword vectors. The
; joystick vector is at offset 24 from this.
;
MOVEA.L D0,A0 ; Must be in an addr reg
MOVE.L A0,ADRSAV ; Save table address
MOVE.L 24(A0),JOYSAV ; Save current joy value
LEA OURJOY(PC),A1 ; Position independent
MOVE.L A1,24(A0) ; Point vector to our code
PEA MOUSOF(PC) ; Command to turn off mouse
MOVE.W #MOUSOFL-1,-(SP) ; Length-1
MOVE.W #25,-(SP) ; Ikbdws()
TRAP #14 ; Xbios
LEA 8(SP),SP ; Tidy stack
```

```
MOVEM.L (SP)+,A0-A1/D0 ; Restore registers
RTS
;
JOYEND MOVEM.L A0,-(SP) ; Save registers
MOVEA.L ADRSAV,A0 ; Point to table
MOVE.L JOYSAV,24(A0) ; Restore old value
PEA MOUSON(PC) ; Command to restore mouse
MOVE.W #MOUSONL-1,-(SP) ; Length-1
MOVE.W #25,-(SP) ; Ikbdws()
TRAP #14 ; Xbios
LEA 8(SP),SP ; Tidy stack
MOVEM.L (SP)+,A0 ; Restore registers
RTS
;
MOUSOF DC.B $12
MOUSOFL EQU *-MOUSOF
MOUSON DC.B $08
MOUSONL EQU *-MOUSON
;
; This next is our joystick interrupt routine. We may use
; registers A0-A2 and D0-D2 without having to save them.
;
OURJOY MOVEA.L 4(SP),A0 ; Pointer to packet
CMPI.B #$FE,(A0) ; Joystick packet?
BLO.S NOJOY ; Ignore if not
YESJOY MOVE.B 1(A0),JOY0 ; Copy joystick 0.
MOVE.B 2(A0),JOY1 ; Copy joystick 1.
NOJOY RTS
;
DATA
;
BSS
;
ADRSAV DS.L 1 ; 4 bytes for table addr
JOYSAV DS.L 1 ; 4 bytes for old vector
JOY0 DS.B 1 ; Joystick 0 state.
JOY1 DS.B 1 ; Joystick 1 state.
;
END
```

Hope this is of help to people. Please feel free to add the contents of this article to any FAQs, etc.

No, you can't rely on effects of XBIOS calls to VDI functions. Might not
work with third-party graphics cards.

2900. MFP yet again

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-27 20:18:54 UTC
From: wallmann@backus.pu.informatik.th-darmstadt.de
Message-ID: <1992Jul27.201854.20396@infoserver.th-darmstadt.de>
Source record: 43401
Body handling: Inline uuencoded payload not displayed: spurious.prg

I have bothered the net for the last couple of years with
this problem. But now, since I feel _really_ confident that
I know what's going on I feel oblidged (oh so oblidged (har))
to bother you once more.

The problem:

```
/* ------------------------------------------------------------
WARNING!! You have to reboot after running this program
------------------------------------------------------------ */
#include <tos.h>

main()
{
unsigned long count = 200000;

Cconws( "Move the mouse, hit the keys!\r\n");
while( count--)
{
Jdisint( 6);
Jenabint( 6);
}
Cconws("Mmmh, either you were lucky or I was wrong :-P\r\n");
}
```

Now these are only TOS calls and you wouldn't expect them to
produce a crash (in an ideal world). Alas they do.

What's happening is that the MFP chip that is accessed here with
the Jdisint, Jenabint (aside: why not Jdis*b*int ?) has a problem
dealing with an interrupt JUST WHEN it's being turned off to this
interrupt source. The Jdisint call in this case is sort of
asynchronously interrupting the interrupt processing of the MFP
(maybe just when communicating with the CPU). [#1#]

Now the MFP doesn't know what to tell the CPU properly anymore
and sends the CPU a spurious interrupt. On the ST though, normally
a spurious interrupt (which can't be masked, coz it's NMI) leads
to bombs!

EVERY program that uses Jdisint (or disables/masks off the MFP
directly) on an interrupt channel which might still produce interrupts
has a slight chance of crashing.

Solution:

a) Programmers that use Jdisint or turn off -active- MFP
interrupts in any way, may want to intercept the exception
vector at $60 and just do an RTE on it.

b) Users who feel that they might suffer from spurious IRQs
install the little ditty appended here, that just ignores
spurious IRQs, and put it anywhere in there AUTO folder.

In article <1992Jul27.100013.28213@bas-a.bcc.ac.uk> ucacmsu@ucl.ac.uk (Mr Stephen R Usher) writes:

>The main problem is that the bus handshaking has totally changed with teh
>'040. On the 680[0123]0 the CPU has the bus by defaults and gives it up to
>peripherals. On the 68040 the bus is "free" by default and is only acquired
>by the CPU when necessary.

I guess I don't understand the implications of having a free bus by
default - do you (can you) explain, or if its too esoteric, perhaps via email?
I have read some of the 680x0 manuals (briefly - it wasn't mine :( ) but
I didn't see anything about this.

>The other problem on course would be adding the '040 FP software to the
>system :-) and hoping that TOS initialises the PMMU in the chip in the
>correct way (the '040 only has a sub-set of the instructions for this that
>the '030 has).

I thought that 3/2.06 and higher was supposed to support 680[01234]0
without any problems - that and the fact that if Atari does come out with
a '040 workstation, its tos better support the '040 too :).

>
>Steve
>
>If you want to know more get the Motorola 680x0 reference manual.

But who will interpret it for me. You _know_ manuals are written in
the most obscure technicalese available so that it is equally obfuscated to
all who read it. :)!

2902. Problems with ARGV

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-28 06:39:20 UTC
From: jensk@hpbbrd.bbn.hp.com
Message-ID: <9130026@hpbbrd.bbn.hp.com>
Source record: 43412

Yesterday I ran into a problem with the ARGV parameter passing scheme that
I'm sure others must have seen before. The ARGV scheme can't pass empty strings
as parameters !
What happens is that Pexec can't distinguish between an empty parameter and
the end of the environment string (both are represented by two consecutive
NUL bytes). In effect, the first empty parameter will terminate the parameter
list.

Since I haven't seen this problem come up previously, I guess that nobody ever
tried to work around it. Anyway, here's a suggestion for fixing it (while
still remaining compatible to ARGV):

- Pass all non-empty arguments via ARGV, ignoring empty ones.
Let's say you want to execute

/bin/arrgh foo "" bar baz "" zip;

you would pass an environment string ending in

ARGV=\0/bin/arrgh\0foo\0bar\0baz\0zip\0\0

- Pass the *positions* of the empty arguments in some other place
(within the environment). Most convenient would be the ARGV variable
itself, but some shells and/or runtime libraries already use that
for other purposes.
Assuming you use an environment variable called 'ARRGH' (just for
demonstration) and pass the positions in ASCII format (dito), this
would look like

ARRGH=2,5\0

in the example above. The C startup code would interpret this by
assigning empty strings to argv[2] and argv[5].

This approach won't break any existing code. If a program or shell doesn't
understand it, it will just keep the old behavior. By incorporating the
mechanism into the C library (startup code and exec() or spawn() or whatever),
programs have just to be relinked to be able to use it.

I'd like to hear the experts comment on this.

Jens.

2903. Need help with odd hard drive problem...

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-28 11:19:50 UTC
From: kendall@flammulated.rice.edu
Message-ID: <KENDALL.92Jul28051950@flammulated.rice.edu>
Source record: 43405

I'm having a strange problem with my HD, and was wondering if anyone out there might know what was wrong:

My st simply refuses to detect my HD at all anymore!! When I try to boot from the HD, nothing happens, and occasionally the floppy drive gets messed up after the boot - all disks put into it show up with 0 byes and 0 items.

I tried to boot from the Atari HD utility disk, but AHDI says "Unit 0: Identification unavailiavble", and after that HDX rufuses to admit that the drive exists even when I try to format. I've checked the cable, which is OK, and everything's plugged into the right place.

Just in case it matters, my system setup is:
520 ST with Tech Sp. 1mb upgrade
megafile 30 HD
external floppy drive.

Any help would be *really* appriciated!!

Thanks,
--

2904. Emacs 18.58 bug

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-28 11:44:26 UTC
From: monnier@disuns2.epfl.ch
Message-ID: <1992Jul28.134426@disuns2.epfl.ch>
Source record: 43406

I installed 18.58 with almost no changes (the only ones were in emacs.rc
where I changed the paths for atari.el and dos-mode.el (well not really
changed but converted from absolute to relative)).

I had one main problem:
when moving downward with the cursor it sometimes (rather frequently)
don't want to stay in the same column: for example, being in the
10th column, when I move downward, the cursor stay in this column
in the first line of each paragraph and gets back to the first column
in the following lines of the paragraph (getting back to the 10th col
when entering a new paragraph).
This would not be a problem if the 'point' changed accordingly (which
is of course not the case): the cursor appears at the 1st col but is
in fact still in the 10th and when I type some chars, what I see is
really not what I get (as I don't write where I believe to).

This at least appears in Text mode. (maybe in other modes too but I
don't remember and I haven't used it long enough)

From: skolodzieski@vaxc.stevens-tech.edu
Message-ID: <1992Jul28.095741.1@vaxc.stevens-tech.edu>
Source record: 43407

Hello,

The problem with Emacs 18.58 not staying in the same column when
moving down a line is due to a bogus termcap entry. I do not know your
setup, but if you use the supplied termcap entry in directory examples,
e.g. :

TERMCAP = <path>/examples/termcap
TERM = vt52

then the above problem should dissapear.

Cheers,
scott.

P.S. perhaps a german reader with access to atari.archive can post he emacs
18.58 to another ftp site, since in the summer a.a does not get updated
so people in general are unaware to the new emacs existence.

2906. Minix 1.6.16 upgrade question

Newsgroup: comp.sys.atari.st.tech

I downloaded the ST and PC upgrade kits and took a peek at what is in them and read through the "INTRO" file from the ST upgrade. My question is this:

Its not clear from the "INTRO" file whether I should use the "include/sys" cdiffs from the PC upgrade. Step 3 says
"apply the include changes from cs.vu.nl However, keep your old a.out.h, stdio.h, ctype.h and signal.h. Do not apply the include part from this upgrade!!"

What does this mean??

Has anybody tried to upgrade to 1.6.16??

Bob Malay

2907. A "C" question...

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-28 20:46:58 UTC
From: MDORMAN1@ua1vm.ua.edu
Message-ID: <16832DDF3.MDORMAN1@ua1vm.ua.edu>
Source record: 43409

I've got a question about how to do something in "C".

I'm in the process of writing a C library to make it easier to manage windows (some of the nasty stuff like outputting text through a printf()-like interface, etc).

I have a structure that describes large parts of the window (things like its current size, the window handle, etc.). One of the things I've been thinking about doing is storing the window name and info fields as part of the structre.

Now, obviously, I don't want to have them allocated if they're not going to be used. So I was thinking of creating functions wx_name() and wx_info(), where the function definition would be something like:

```
wx_name(ws,str)
Window ws;
char *str;
```

I would then like to malloc() memory to hold the string that we've been given so that we won't use any more memory than necessary (I have an ulterior motive, I want to create a printf() interface to this stuff, too--I have a couple of programs that could use it).

So, what's the best way to declare the variable within the structure? Is merely making it a char * sufficient, or do I need to make it static char *?

I never have been able to figure out just what the difference is in practical terms. If someone could explain, I'd be deeply indebted.

Mike.

2908. ST monitor connector pinouts?

Newsgroup: comp.sys.atari.st.tech

Could someone tell me what the pinouts are on the monitor plug? I just discovered that I can plug an ST monitor into a Sega Genesis game system, if I can just build the cable. I know that it's shown in the ST owner's manual, but manual's at my parents' in Portland.

The monitor's an SC1224 and goes to a Mega ST 4 (no "e").

Hi there,

Can somebody encode some copies of printer drivers for First Word Plus
and Degas Elite compatible with a HP LaserJet Plus, and either post them
to me or to comp.binaries.atari.st....

Is there a repository for such items somewhere in the net.world or ftp.world?

Many many many thanks in advance.

2910. Dear Mr. Very Competent Technical Person

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-29 03:53:19 UTC
From: wisner@netcom.com
Message-ID: <xanmwtb.wisner@netcom.com>
Source record: 43413

I recently pulled my 1040STfm out of storage after moving and have a few questions about this aging beast that hopefully you, Mr. VCTP, can answer.

First, the keyboard needs a good cleaning. This is nothing new, and I've done it before. But does anyone have any particularly effective cleaning methods to recommend? How much does an entire replacement keyboard generally run? I certainly wouldn't mind a fix for my mushy space bar.

My SM124 monitor is very flaky. After it's been on for about 20 minutes, the screen simply blacks out. There are no problems before this and the monitor still has power (LED/sound), it just goes. From the behaviour, I've started thinking it might be overheating in some way. Now, my strictly limited technical prowess doesn't extend to monitors, so can someone who really knows what he's talking about perhaps help me?

Finally, I'd appreciate recommendations for good Atari service people here in the San Francisco Bay area, perferably Santa Clara Valley. If you're not local, pretend I didn't write this paragraph.

Yours,
Depreciating in Mountain View

I didn't think that you could use the ST monitor for the Sega?

Where did you see this?? How??

Now as requested for all to see the pin outs...

Pin 1 - Audio Out
2 - Composite Video (W/modulator)
3 - General Purpose Output (From PSG chip)
4 - Mono Detect (PSG port line again)
5 - Audio In
6 - Green
7 - Red
8 - +12 Pull Up
9 - H Sync
10 - Blue
11 - Mono Video
12 - V Sync
13 - Gnd.

Looking at the cable, pin one is right of the connector key.

The Sega Genesis puts out a signal line with Hsync & Vsync combined.
How do you make it work the SC1224???

I agree with C. Tim, if you must warp the mouse in your application, then
please add an option to turn this off from a configuration file.

Heuer's Law: Any feature that cannot be turned off is a bug.

Hi,

Anyone had this problem? My ST keeps resetting itself when I boot it (from diskette). It does read the prg's in the auto-folder as well as the acc's but as soon as the desktop comes up, it resets. This sequence then repeats and repeats and repeats until I'm fed up. So, I've put it far away in a cupboard... Who knows what could be the cause of this and what needs to be repaired? Tell me!

Well, that's a known problem :-) Fortunately, empty parameters mostly occur as parameters to 'test', and this is normally (or can be) a builtin command of the shell.

Your proposal for an ARGV extension seems to work. If 'we' all (MiNT-Libs, and GNU-Libs, PureC startup code and so on) agree on this, that could be a solution...

I had the same problem with my VORTEX hdplus 30. I have a SH205 as 1. and the
hdplus as 2. HD. When I used HDX version 4 and 5 I got for the VORTEX HD the
mentioned message at boot time and the VORTEX was not available.
The solution was to use my old HDX I think it is version 3.

Not so. I found this problem just recently, while working on 'grep'.
If 'grep' is passed an empty string for the pattern, it is suppose to match
every line in the file, since the pattern is normally bracketed with
".*(pattern).*" when no anchoring is used. It took me about three nights
to figure this out.

>Your proposal for an ARGV extension seems to work. If 'we' all (MiNT-Libs,

Well, I've been working on an ANSI/POSIX library for Sozobon C 1.2. I've
provided my own C startup that supports ARGV. If you're going to do
this, which seems reasonable, you'll have to pick a better name than
ARRGH for the env.var. since it has no meaning. Something like

ARGV_EMPTY=index1, index2, ... indexN\0

would be more acceptable.

MDORMAN1@ua1vm.ua.edu (Mike Dorman) writes:

```
: I've got a question about how to do something in "C".
:
: I'm in the process of writing a C library to make it easier to manage windows
: (some of the nasty stuff like outputting text through a printf()-like
: interface, etc).
:
: I have a structure that describes large parts of the window (things like its
: current size, the window handle, etc.). One of the things I've been thinking
: about doing is storing the window name and info fields as part of the structre.
:
: Now, obviously, I don't want to have them allocated if they're not going to
: be used. So I was thinking of creating functions wx_name() and wx_info(),
: where the function definition would be something like:
:
: wx_name(ws,str)
: Window ws;
: char *str;
:
: I would then like to malloc() memory to hold the string that we've been given
: so that we won't use any more memory than necessary (I have an ulterior motive,
: I want to create a printf() interface to this stuff, too--I have a couple of
: programs that could use it).
:
: So, what's the best way to declare the variable within the structure? Is
: merely making it a char * sufficient, or do I need to make it static char *?
:
: I never have been able to figure out just what the difference is in practical
: terms. If someone could explain, I'd be deeply indebted.
:
: Mike.
```

```
(1) Have you tried declaring the member of the struct as static?
This should be impossible.
The difference between static and non-static variables is that
non-static variables just exist on the stack (as long as the called
function is active). When you leave the function the space for them
is "recycled" and their value therefore lost.
Static variables are like global variables because they exist as long
as the program is running and their value is never lost. They can
however only be accessed in the function in which they are defined
(as opposed to global variables). So when you call the function again
you can be sure that they have the same value as after the last call
of that function.
```

As the char-pointer isn't a variable but only part of a variable
(namely the struct Window ws), it can't be made static.

Static variables are very rare (on the atari anyway), and I don't
think you'll need them in this program.

(2)
Assuming that the struct Window looks something like this:

```
typedef struct {
.
.
char *name;
char *info;
.
.
} Window;
```

The function wx_name could look like this:

```
int wx_name( ws, str )
Window *ws; /** use pointer to struct **/
char *str;
{
ws->name = (char*) malloc( strlen( str ) + 1 ); /* add 1 for 0-Byte */

strcpy( ws->name, str );
}
```

You should pass a pointer to the struct to the function because passing the
struct itself will either not work at all or every single member of the
struct will be passed to the function (pushed onto the stack) instead of
just the single address, which is of course a lot slower. (Maybe this was
just a typo?)

Remember to free the individual pointers (free(ws->name)) before freeing
the struct or you will have a lot of zombie-strings using up small chunks of
memory that cannot be allocated again.

Hope this helps, Stefan

More to the point: is there anybody out there who has never had this problem?
What is probably happening here is dust or disturbed magnetic particles on the
boot disk. During the booting something in the GEM system area gets trodden on,
so as soon as the desktop tries to come up it falls over. It is also common for
the machine to hang or reset before the desktop appears.

How to prevent this from happening:

1) Never leave disks in the drives unless they are being accessed once in a
while, dust settles on the disks. This is why some double-sided floppies fail
and become only useable as single-sided floppies (dust does not settle on the
underside) and why single-sided floppies tend to last a lot longer.

2) Never ever switch the power to the ST on or off while a disk is in the
drive. Electrical spikes from switching the power often cause magnetic glitches
on the disk. Yes, I know it says in the manual "Insert boot disk and then
switch on the power". Instead, switch on the machine _without_ a boot disk,
press and hold the reset button while you insert the boot disk, then release
the reset button. I had regular floppy disk failures before I realised this.

>and repeats and repeats until I'm fed up. So, I've put it far away in a
>cupboard... Who knows what could be the cause of this and what needs to be
>repaired? Tell me!

A quick guess - you have an AUTO program and/or desk accessory which is either corrupted or won't work on your ST. Typical programs which can cause the activity you see include: monochrome emulators, STe-specific AUTO programs or desk accessories run on an ST (and, sometimes, vice versa), and screen accelerators run in the wrong resolution (e.g. QUICKST - color version - run on with a monochrome monitor).

Some quick suggestions to determine an offending program:

1. Try to boot up without a diskette. If the GEM desktop comes up, you've got a problem with one of the AUTO programs and/or desk accessories. If you still have the reset problem, it's hardware related.

2. If GEM boots up in (1), place the diskette with your AUTO folder into the disk drive and do the following:

a. Rename every file in the AUTO folder to xxxx.PRX

(example, rename FOLD100.PRG to FOLD100.PRX)

b. Rename very accessory in the root directory to xxx.ACX

c. Rename =one= AUTO program normally

d. Shut off your ST, wait for about 20 seconds and then turn it on.

e. If the system does not reset repeatedly, rename =one more= AUTO program normally and repeat (d). Do this until all AUTO programs have their normal names OR until your ST constantly reboots. The last program you renamed is causing the problem. Reboot without a diskette, insert the boot disk and remove/replace the offending file.

f. Test again until all AUTO programs and desk accessories are normally named and the reset problem does not reoccur.

I too have the same problem. And came to the same solution. (i.e. ignore it
and write it off to 'the drive wasn't awake' kind of thing) But testing it, this
answer doesn't logically follow, its seems completely random in nature. And since
it will (usually) boot the second time, I haven't worried about it. ICD stuff
mentions about SCSI drives having some bug about intially start up, and ICD has
a patch for some drives (but not mine) but it doesn't even seem to be this
problem.

Anyone else know what going on.
Jim

Source record: 43427

A lot of people have been putting up explanations for the original poster's problem with booting from the disk drive - and for all I know, they are probably right.

However, I have had a similar problem, but from Hard disk, and it has never been serious enough to worry about it (so I haven't) but I wonder if anyone else has had this happen. Almost every time I boot my computer (NOTE: this is _not_ every time), it will bomb with a couple of bombs (don't remember how many), then it will restart and load just fine. I used to half-heartedly explain it as "the drive wasn't as awake as it should've been", but I don't really believe that is the problem. I know that there are some programs that work by loading and then resetting the computer which boots normally, however I don't believe I have any autoprogs that do that. Just in case, in my auto/ is: Fatspeed,date/time fix prg (ala ICD), QuickST (small version of 2.2), and randplay (but that is a recent addition).

Any ideas?

-Mike

2927. Questions for hardware hackers

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-29 20:18:57 UTC
From: gt1448b@prism.gatech.EDU
Message-ID: <64628@hydra.gatech.EDU>
Source record: 43428

The June issue of ST Format (UK) had an article on memory upgrades. I am interested in expanding my 1040ST to 4 meg so I read it. Most of the upgrade boards discussed were restricted for use with square MMUs. My ST has the rectangular MMU. I read in the Toad Computer catalog that some MMUs will not work with more than 1 meg. Are these rectangular chips those MMUs? I noticed that near the MMU there are pads marked 256K and 1M where the 256K pads are bridged by a blob of solder. Does this have anything to do with the MMU configuration?

Another thing caught my eye in the ST Format article. It showed the different ST mother boards that have been used. The one corresponding to my ST motherboard noted space on the board for the blitter chip. I had noticed that space and wondered what chip it was for. I assume that I can easily add a blitter chip to my ST. Are blitter chips readily available? Should it be socketed? What kind of socket would I use? Here too I noticed pads bridged by a blob of solder where the traces lead to the pins of the (missing) blitter chip. Does that affect blitter operation?

Thanks in advance for your response.

> ARGV doesn't allow passing empty arguments
> use another env var to pass the position of the empty args

I don't like it. It sounds needlessly complicated to create a whole
'nother env var for this.

I have two variations on an idea for coping with this. The first variation
assumes that we never pass binary values in the ARGV. (IE, isprint() is
TRUE for all chars appearing in the args in the ARGV area.) In this case,
I'd recommend using \001 as a placeholder for an empty arg. Using this,

grep "" *.c

would be passed as ARGV=\0grep\0\1\0*.c\0\0. If my assumption is invalid,
and folks do pass binary data in ARGV, then use an escape system where an
empty arg is \1\1, but a true binary 1 is \1\2. (You could even extend
this to allow passing binary zeros, escaped as \1\3 for example.)

Thoughts?

In a word: Bullsh*t. I've had this 1040ST for seven years now. I leave
the same disk in the drive all the time; it's almost never accessed. I rarely
power down at all, but when I do, I do it with the disk in the drive.

I've never ever had a problem I can attribute to either of these habits.
I do, however, thoroughly clean the machine inside and out twice a year.

> pinouts, timings, functionality of Atari custom chips

Atari has never released really detailed info on the custom chips, other
than the DMA chip. Some books (ie, Atari ST Internals) have pinouts for
the Glue chip and so on, but nothing like timing diagrams, or even detailed
functionality descriptions. Of the custom chips that can be programmed
(Blitter, DMA, etc), the Atari developer docs provide pretty good info,
but still not to the level of timing diagrams.

>empty arg is \1\1, but a true binary 1 is \1\2. (You could even extend
>this to allow passing binary zeros, escaped as \1\3 for example.)

I was thinking something along these lines, also. What I was thinking about
was using a single space to signify an empty argument. Then, for arguments
that consist of spaces (fairly rare, I'd think), a space is added to the
string. A program using this convention (or compiled with a runtime that
handled it) would subtract a space off any argument that consisted of
only spaces.

The question is, of the schemes mentioned so far (or related ones), which
would break the least of the existing ARGV programs? (I vote for mine :-))

Concerning random resets when booting up...

I believe it was Charles F. Johnson of Codehead Technologies who said there's a bug in the way the system handles date/time changes that may cause crashes seemingly at random.

Try temporarially removing the date/time setter and see if that cures the problem... if that's it, the only thing you can do is learn to live with it... (as I have...)

Hello Fellow news group readers,

We finally have the FoReM NeT (FNET) news in fido and usenet formats
for the whole world to read.

I would like to start polling in a 10 days time for a NEW news group of
this one called comp.sys.atari.ZNET . This will reflect the Z*NET FNET
mail / traffic on Usenet.

As we are the mail gateway for Z*NET on the nets we will send the mail
both directions from here in NZL.

Before I poll I would like some feedback if any from this news group.

Kind regards

>so as soon as the desktop tries to come up it falls over. It is also common for
>the machine to hang or reset before the desktop appears.

This might be a cause for such a problem but it does not hold for me. ALL of
my disks won't work anymore (and they are *not* infected :-) and booting
without a disk won't work either. So thanx to everybody who suggested that it
might have been corrupted auto-prg's or acc's but it's not the case for me...
So it must be a hardware problem. I expanded the memory to 3 MB recently and
before I had some troubles with an overheating power supply. My machine is
a 1040STf with tos 1.0. Any other suggestions?

I have version 6.92 of MDisk and it won't work with MiNT, even if I
set MDisk up so that it installs the ramdisk in ST-RAM. I'm running MDisk
on a TT with TOS 3.06. When I install MDisk either at boot up or by
activating it from the accessory menu I get about 11 bombs including the
same number of MiNT messages and then the program freezes up.

>ARRGH for the env.var. since it has no meaning. Something like
>
> ARGV_EMPTY=index1, index2, ... indexN\0
>
>would be more acceptable.
>

So where does this environment variable go ? Before ARGV ? Then programs
that don't understand will pass it onto their children, so we need *another*
flag to say the information is valid. Yeeuch!
After ARGV ? How do we tell we are after ARGV, if the double null is possibly
just a null parameter ? The information we need is somewhere else...
(Think about this:

prog.ttp arg1 "" ARGV_EMPTY=foo bar bletch

(yeah it's unlikely, but *possible*)

It looks like there should have been a length flag somewhere or maybe
some other terminator than \0\0.
The other solutions I've seen have problems too:
1) escape characters (\001 etc) will really confuse older programs.
2) adding spaces doesn't seem too bad, but there has to be a tidier fix
than this.

I'd say put a length flag or the value of argc somewhere. I'd suggest
breaking MWC programs and putting "ARGV=argc\0arg1\0arg2\0\0arg4\0\0"
if MiNT can pass open file descriptors to processes' children. I think
something somewhere will be broken by whatever method we choose, and

this one at least is aesthetically more pleasing.

As an aside, who else is still using Sozobon 1.2 ? Can anyone tell me
why I should move to Sozobon 2.0 or 1.33i ? What's the difference anyway ?
What does Heat'n'serve mean ? Have either of these fixed all the short==int
assumptions in the source that threw me when I built it as a Sun-based
cross compiler ? (I seem to remember somewhere a `#define short int'
somewhere !!!)
I'd like to make sure my programs will run with MiNT (when I can afford
to upgrade from 1 -crowded- meg), so is there a MiNT friendly libc ?
(the dlibs I have uses tight loops for sleep() etc.)

Is anybody out there using MiNT on a 1040st ? How ? What shell are
you using ? Tcsh seems to be too big, and gulam doesn't understand job
control. (I don't want to know about bourne-shell lookalikes I'm a BSD
man.)

: >repaired? Tell me!
:
: A quick guess - you have an AUTO program and/or desk accessory which is either
: corrupted or won't work on your ST. Typical programs which can cause the
: activity you see include: monochrome emulators, STe-specific AUTO programs
: or desk accessories run on an ST (and, sometimes, vice versa), and screen
: accelerators run in the wrong resolution (e.g. QUICKST - color version - run
: on with a monochrome monitor).
[stuff deleted]

Another possibility is that all programs work just fine on your ST individually but crash when you put them together on one disc because they are not 100% compatible. This usually involves just two programs that simply won't work together. Try to find out which ones they are by copying different combinations to another disk, then decide which of two you can live without.

Hope this helps, Stefan

Not powering down (except for maintenance and repair) is a good way to extend
the useful life of the hardware as well. Voltage spikes are nasty, and are
not entirely eliminated by the capacitors. I'd say you were lucky to get away
with nil floppy damage over 7 whole years. My first impression after moving
from Sinclair microdrive cartridges to floppy disks was how robust disks are.
Nevertheless, I had regular failures until I started observing these two
practices that I mentioned. Instead of a 60-90% likelihood of damaging the
media (microdrive tape) it had become 5-20% (floppy disk). I have noticed that
floppies are sensitive to power surges on Atari ST, PC clones, Macintosh,
Sinclair QL, CP/M systems. I know of some floppy-only PC computers which are
left 24 hours a day, 365+ days of the year serving as IP routers. If the boot
disks (left in the drives at all times) are not replaced at regular intervals,
then the probability of eventual failure (often within a year) has been shown
to be high.

>and you are not 100% satisfied with the animation I'd suggest that you
>use the VBL directly to flip pages (you can use Setscreen()) there too.
>Until then Setscreen() + Vsync() + frclock will suffice.

The trick is to set the physical screen base before the last frame that you
are waiting for. ie. If you are running at 3 frames per turn then set the
new screen address when you reach a count of two (which means the current
screen is being displayed for a third time) so that it takes effect at the
end of frame three. "Why?" I hear you ask (or maybe I don't:-).
Well if you set the physical screen base the SHIFTER chip will not use that
address until it finishes scanning the current screen. However this happens
before SHIFTER causes the vertical blank interrupt so if you change the
screen address in a VBL interrupt then you are too late.

You want more proof? Take a look at the system variable 'screenpt' ($45E).
The system VBL routine copies this to the physical screenbase if it's non-zero
but foolishly neglects to zero it afterwards. You might think that this is
the variable that Setscreen sets. Nope. Setscreen blasts the hardware itself
and ignores screenpt. In fact TOS *NEVER* writes to screenpt. If you do
then your in trouble because that means that the screen address is getting
changed to screenpt every VBL thereafter EVEN after a soft reset. Can you
imagine coming up with a 4MB machine in which the video RAM is at a low
address in memory belonging to no-one. Why did Atari do this? Because they
originally thought that screenpt/VBL would be the way to ensure a clean
screen change but in the end the video hardware took care of it and the
method became redundant/unworkable. However there are dark grey clouds on the
horizon regarding this issue ...

Don't pass a struct on the stack (if typdef Window (strut window *) then OK). Its messy, slow and how do you return your results to the original struct as you're only working with a copy.

>: I would then like to malloc() memory to hold the string that we've been given

Yes I do this on memory intensive applications. Where strings are likely to be common, I save them in a struct for later searching and re-use.

```
struct string {
struct string *next;
char *text;
};
```

Warning, for read-only strings and also **slow** but if you need the memory...

> (as opposed to global variables). So when you call the function again
> you can be sure that they have the same value as after the last call
> of that function.

Thats their use inside a function. The are also used inside a module at the outer level to define variables in the data seg that are not exported from that module. eg if you had a prog made up from main.c, mod1.c & mod2.c you could define

```
static char *foo;
```

in each and they would not interfere.

> Static variables are very rare (on the atari anyway), and I don't
> think you'll need them in this program.

Sri, I beg to differ. They are a very valuable tool & you will find many library routines that return a char * from some other parameter(s) use the mechanism to store their string (otherwise they would not work). eg

```
(char *)ctime((time_t *));
```

That would be implemented as:

```
char *
fn(clock)
time_t *clock;
{
static char result[LENGTH];

sprintf(result, FORMAT_STRING, ARGS....);
return result;
}
```

Hope this helps you understand what is going on.

John

>this to allow passing binary zeros, escaped as \1\3 for example.)
>
> Thoughts?

Am I missing something? It seems all too easy for me. Why not pass ARGC ?

so in the above example:

ARGC="3"

(assuming the cli does not interpret the *.c) and

ARGV="grep\0\0*.c\0"

(yes there are 2 \0 's on the end --- remember a str is terminated by \0)

then the startup code mimics
```
tmp = argc = atoi(getenv("ARGC"));
while (--tmp) {
. argv processing
.
}
. argv tidy up
main(argc, argv);
```

and you can pass null strings, binary data (as long as it does not
contain \0) as much as you like.

I don't know. My first thought was software incompatibilities. It sounds
like some TSRs and desk accessories are conflicting, at least from the little
that he tells us. :^)

First off, 3MB? I've never ever seen that memory configuration. Oh, well,
live and learn.

If the machine doesn't boot at all, even with no disk in the drive, it's
a memory upgrade problem. My Z-Ram 3-D board was quite dodgy there for a while
and would display the same problems your machine would. Check your connections
look for cold solder joints, make sure any cables are really close to the
motherboard so they won't act as antennas

Hope this helps,

Mike.

Anthony Howe (ant@mks.com) wrote:
>Well, I've been working on an ANSI/POSIX library for Sozobon C 1.2. I've
>provided my own C startup that supports ARGV. If you're going to do
>this, which seems reasonable, you'll have to pick a better name than
>ARRGH for the env.var. since it has no meaning. Something like
>
> ARGV_EMPTY=index1, index2, ... indexN\0

Sorry, that won't work (Stefan Eissing, author of Gemini, pointed that out this afternoon :-). Why?

There's no way to verify if this environment variable has really been created by the parent process. Example:

Shell: starts process 'A', creating ARGV_EMPTY
Process 'A': ignores ARGV_EMPTY and launches process 'B'
Process 'B': knows about ARGV_EMPTY and uses it

So we'll have to put the additional information into the 'normal' ARGV area.

From the proposals made, I currently prefer this one:

Caller

Replace an empty argument by one blank. Add a blank to all strings that contain only blanks.

Child

If an argument contains only blanks: make it one character shorter.

Of course, this new method *could* be signaled by a string in the ARGV value (which is normally unused). However, I am not sure whether that will break existing programs (MWC?).

2949. GEM menu bar garbled

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-30 21:30:09 UTC
From: snoret@egon.unx.sas.com
Message-ID: <Bs8129.1rl@unx.sas.com>
Source record: 43299

I have a strange problem that I cannot get rid of. It's been happening
for a while, but only recently have I started using medium and low resolutions
for anything but games.

Here's my problem: If I boot with my 1040STf with my SC1224 color monitor
AND my Supra 20MB Hard Drive, the GEM menu bar is garbage, as are any drop
down menus and windows (from DA's, etc.) This ONLY happens when I boot
off of the hard drive. If I use a floppy, or even nothing at all (straight
GEM boot from ROM) I don't have the problem.

And it doesn't seem to matter if I auto run anything from the auto folder
or not (all I've got in there is pinhead, anyway). DA's don't seem to impact
the behavior either. A resolution change doesn't help, either.
What is wrong, and do any of you wonderfully knowledgeable (sp?) people
know how/if I can fix it?

Thanks in advance.

Rick

Is it possible to network two STs together using the DMA port? For example, if I wrote a bit of machine code that sent a byte out the DMA port, could another machine read it in on its DMA port?

Just curious,

Thanks,

Dan

It must be possible though, because the setup DA for Turbo ST does it.
Annoys the hell out of me. :-) Since it's the only thing I've got
that does it, I'm already moving the mouse down from the menu bar
where I activated the DA, to the alert box... but it's already there,
so I have to back up.

So, just buy Turbo ST and disassemble the DA. :-Q

Maybe the problem is your strange memory configuration. The MMU of the 1040STF
can only handle two memory banks with either 512K or 2MB. So a 1MB machine has
two banks @ 512K. If you want to upgrade by 2MB you'll have to disable one of
the 512K banks giving you a total of 2.5MB.

Hope this helps, Stefan

Yes, you ARE missinng something. On Pexec, GEMDOS copied the environment
to a newly allocated buffer. And guess how many bytes are copied? Upto
the first \0\0 :-(((

>I'd say put a length flag or the value of argc somewhere. I'd suggest
>breaking MWC programs and putting "ARGV=argc\0arg1\0arg2\0\0arg4\0\0"

This sounds pretty good too. Having never used MWC, could someone
explain what MWC startup code uses the first ARGV parameter for?.

Idea 1

Since most C startup just scan the environment for string "ARGV", why
not encode argc in the ARGV name:

```
ARGV6=<MWC stuff>\0arg1\0\0arg3\0\0argv5\0\0

^^ Place argc here in the name. It is then left to the
C startup to correctly parse the env. for /ARGV[0-9]+=/. This is by no
means perfect solution for old programs, especially if their C startup
looks for the string "ARGV=" instead.

Idea 2
------
An alternative would be to place the encoded string of empty positions
_after_ the double NULL.

ARGV=\0arg1\0arg3\0arg4\0\0EMPTY=2,5\0\0

would represent

argc = 6;
argv[] = { "", "arg1", "", "arg3", "argv4", "", NULL };

The ARGV could be left and parsed as it always has by older programs.
Newer ones could check immediately following the double NULL for the
EMPTY string list.

>if MiNT can pass open file descriptors to processes' children. I think

>
> As an aside, who else is still using Sozobon 1.2 ? Can anyone tell me
>why I should move to Sozobon 2.0 or 1.33i ? What's the difference anyway ?
>...

The only reason I still use 1.2 is because I have the source. The other
versions seemed too unstable at the time and without source. I decided to
wait till a stable version with source was released. I'm still waiting.
It would be nice to have longer names, handle ANSI prototypes, be able
to switch between int == short and int == long, allow structures and
arrays to be greater than 32K, and use long for array indexes.

2957. Supra Hard disk Utilities

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-31 16:15:17 UTC
From: "Gerry O'Rourke"
Message-ID: <1992Jul31.161517.18648@nt.com>
Source record: 43341

Hi!
I am looking for the latest Supra Hard Disk Utilities.
I have tried the obvious place (Supra' s Tech support BBS), but I could not download any files. Are they available by FTP?
I have recently got hold of Atari's AHDX5, but I don't really want to abandon Supra completely, unless:

(a) AHDX5 is way ahead of the latest Supra stuff.

(b) Supra are getting out of supporting Atari ST's.

I left a message for the SysOp, explaining my difficulties, but when I checked back several days later, there was no reply.
Is there some Supra approved dealer in Europe (all I can find are ICD adapters in the magazines)?

Also, is the limit for (standard) Gem partitions (32Meg- using Tos 1.4) increased in Tos 2.06.

Thanks in advance

Gerry O'Rourke

2959. Continuing 1.44 Drive Woes

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-31 17:07:59 UTC
From: "J.J. Lehett" <JJL101@psuvm.psu.edu>
Message-ID: <92213.130759JJL101@psuvm.psu.edu>
Source record: 43312

Well, having bought a Tos 2.05 MSTe 4/50 with a 1.44 drive in it, that
was not working, I have now upgraded it to TOS 2.06, and installed a newer ajax
chip. However still no luck. From the desktop the machines ALWAYS fails a
format of a HD disk somewhere very soon after the 40th track.
I have tried disconnecting the power to the hard drive to see if it was a
power supply problem, but the same thing continued. Thus, I am not at a
complete loss as to possibilities. I changed to newer TOS, a new Ajax chip,
and reduced the load on the power supply, without any noticeable change to
the formatting of HD floppies.
Anyone have any further suggestions?

Date: 1992-07-31 17:46:31 UTC
From: wallmann@backus.pu.informatik.th-darmstadt.de
Message-ID: <1992Jul31.174631.29070@infoserver.th-darmstadt.de>
Source record: 43310

```
---------------------------------------------------------------
HACKING-CONTEST
---------------------------------------------------------------
Change the screen color on a normal ST using only those XBIOS,
BIOS and GEMDOS calls that have been available since TOS 1.2 in
-as many different ways- as possible. Each entry is scored
according to this table:

Changes color voluntarily +7 pts ; these two are of course!
Changes color +4 pts ; mutually exclusive
Being resolution dependent -1 pts
Crashes after changing color
or terminating -2 pts
Crashes w/o changing color -3 pts
Used same idea with a different
system call 1 pts max. for this entry
Used small modification of the
same idea with the same system
call 0 pts max. for this entry
Uses any non-TOS calls anywhere 0 pts max. for this entry
Uses Supexec or Super anywhere 0 pts max. for this entry

Solutions depending on special hardware can not be accepted.

With changing colors voluntarily I mean, that you have full control
over the (16-bit) color value.
All points are added, the one with the most points wins!
You have to accept that the way points are given are solely my own
judgement.

Each entry should be a *seperate* little source of working
code in C and/or assembler. Please write as compiler/assembler
unspecific as possible. A comment here and there might help.

Remember: Just use XBIOS, GEMDOS and BIOS calls, that have been
available since TOS 1.2.

*********************************************************
* The end of the contest is 23.59 of Sunday (9 Aug. 1992) *
* Mail your entries to: *
* wallmann@backus.pu.informatik.th-darmstadt.de *
* Use this in your "Subject:" line: *
* CONTEST: <yourname> ANONYMOUS: [n/y] ACK: [n/y] *
*********************************************************
```

You may indicate whether you want an ACK that your entry has arrived,
and also you may choose to remain anonymous if you so desire. You can
of course use an assumed name as <yourname>, which will then be used
in the final result list. You may send in your entries trickle-like
one after the other. You may send your code uuencoded in .ARCed,
.ZOOed or .LHArced form.

The winner(s) will receive (for lack of sponsors) a purely symbolic
prize in form of a custom "SO WATT Carebears Demo"-ripper.
Of course the results and all the code examples will be posted to the
net.

Nat!

HINT: With <way> I don't mean just setting different colors or using
LSR.W instead of MOVE.W or using the same method accessing different
memory locations.

Have you tried booting with nothing in the disk drive? Your problem sounds
to me like you have some incompatible programs in your set-up. If the
desktop appears, change the last letter of the suffixes of the ACC's and
PRG's to X so they won't operate and try again.

If it boots now, change the programs back one by one. When it bombs out
you've found the culprit.

2962. Re: Problems with ARGV - summary of ideas posted so far

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-31 18:38:12 UTC
From: ilepore@nyx.cs.du.edu
Message-ID: <1992Jul31.183812.4425@mnemosyne.cs.du.edu>
Source record: 43313

On the problem of passing empty/null arguments via ARGV, we've had so far:

- Creating a new env var that indicates the position of the empty args. This is workable, but the drawbacks are extra complexity, and the need for yet another flag of some sort to validate this new variable so that it doesn't get misinterpreted when passed to children of the application it was intended for.

- Using an escape character or sequence such as \1 to indicate an empty arg. This is workable, and very easy to implement. The drawback is that it may confuse current applications that don't expect \1 chars in args.

- Various schemes that involve \0\0 sequences in the ARGV part of the environment. These won't work because GEMDOS won't copy the data following the \0\0 when it creates the env data for the child process.

- Use a single space to indicate and empty arg. This is especially easy to implement, but locks out the possibility of ever passing a single space as a valid arg. It could be extended to add an extra space to any arg that ends in a space now, but then on the receiving end these have to be filtered out again, so it gets a bit complicated.

So which one do we use? I'd like a relatively quick answer, so that it can be added to HSC 1.40 before its impending release in a week or two. I'm still kind of partial to the escape character, I think. (Not surprising since I suggested it, huh?) Perhaps we could choose a different escape char, one that wouldn't be as likely to confuse an unaware program? We could use an existing whitespace char, \t \r or \n as the escape char that means an empty arg. (I'd vote for \n, I think, it has a certain "nothing here" implication to it.)

2963. Sozobon 1.2, 1.33i, 2.0, Heat-and-Serve

Newsgroup: comp.sys.atari.st.tech
Date: 1992-07-31 19:04:46 UTC
From: ilepore@nyx.cs.du.edu
Message-ID: <1992Jul31.190446.5353@mnemosyne.cs.du.edu>
Source record: 43316

Sozobon v1.2 is the first release that can rightly be said to have really worked at all. Not that it worked well, mind, there's a large variety of codegen bugs and sequences in source that can gracelessly crash the compiler. You have to be well on your way to being an ST (and to some degree unix) guru just to install the compiler and do a Hello World program. A beginner has little chance of getting this beast installed and configured without help.

Sozobon v2.0 is v1.2 warmed over. It adds long external identifiers as a new feature, but little else. All the codegen bugs from v1.2 are still there. It also includes a debugger, which will work with all other versions of Sozobon or HSC as well.

Sozobon v1.33i is my modified version of Sozobon v1.2. I dubbed it the "Heat-and-Serve" release, because it comes with an INSTALL.PRG that installs and configures the compiler for you. At the end of the install, you can just double-click on EXAMPLES.MAK (or, for CLI users, cd examples;make) and it's up and running, compiling a test suite for you to ensure the installation was clean. v1.33i is basically v1.2 with lots of bugfixes and a fair number of new features. The new features include desktop-friendliness, for those (like me) who hate using a CLI, and a variety of extensions that move toward ANSI compatibility. (EG, #else, #error, #line, #pragma handling; adjacent string literals are concatenated into a single string; things like that.) The optimizer in 1.33i is improved with lots of new peephole sequences. All the compiler pieces are faster, generally at least 50% faster, than 1.2. Source code that would crash 1.2 is accepted by 1.33 in most cases. (And, when a bad code sequence is encountered that confuses it, it gets reported like any other error, instead of just putting bombs on the screen.)

To avoid confusion with ongoing releases of Sozobon (v2.0 was released by the sozo crew just after I had released 1.33i; I thought they had gone out of the ST business), I've changed the name of my versions to Heat-and-Serve C (HSC) from now on. Version 1.40 is in testing now, and should be ready for release in a couple weeks. New things in 1.40 include:

- More improvements towards ANSI compatibility (still not prototypes yet) including #elif handling, proper handling of function-like macros.
- Codegen bugfixes; library routine bugfixes.
- Full ARGV support on all tools, compiler pieces, and programs created with the new compiler/library.
- The compiler runs properly as a MiNT background task now.
- The optimizer is WAY faster (eg: one module that used to take 7 minutes to optimize now takes 90 seconds); this affects mainly the worstcase situations like huge functions to be optimized.
- You can now access arrays of any size. In general, pointer math is much more compliant than it used to be. size_t is still unsigned short,

and sizeof(int) is still hardwired as 2 bytes. Despite this, you can use a size_t type to index into an array bigger than 32 or 64k. (But, if you ask for sizeof(hugearray) it'll give you a loss-of-significance error).
- You are still limited to 32k on the size of any single structure, but you can have arrays of structures that exceed 32 or 64k total. (I humbly suggest that if you have a structure bigger then 32k, it might be wise to reconsider your design; there are certainly other ways to skin that cat).

Well, that about covers it. There's a zillion other little things that have been enhanced in 1.33i and 1.40 that I haven't mentioned. (Oh -- full support for void* types was added to 1.33i, forgot to mention that.)

Just a small clarification here (sorry!). I was suggesting adding an extra space only to args that were all spaces. In a more mathematical statement, this means any string of n>=0 spaces is mapped to a string of n+1 spaces.

Of course, that doesn't make the implementation any simpler, actually a bit harder, but it seems to make more sense to me.

>format of a HD disk somewhere very soon after the 40th track.

The problems you are experiencing may be due to noise from the power supply corrupting the data traveling trough the floppy drive flat cabling. The higher frequency of the high density data trsnsmission makes it more susceptible to this noise. The offical Atari installation documentation includes explicit instructions from the routing of the flat cabling to avoid the power supply induced noise. It also explicitly describes the formatting problems you are having as an indication of improper cable routing.

You can also have the cables routed correctly and still experience the problem. Early(there is no clear definition of this) units were shipped with an additional center grounding screw within the power supply housing. It was found that removing this screw reduced the noise level and the high density drive problmes went away. Models currently shipping have this screw removed at the factory. This is not-trivial to remove and if you do not know what your doing do not attempt to open the power supply housing. This is provided for information only.

Another possibility if you did the installation yourself is the reversal of the data ribbon cable into the floppy drive. Pin 1 is reversed on the high density drives from the position that it is in for a double density one. Easy to miss that one, although you would probably have more sever problems.

I hope this helps,

I like HSC a LOT, Ian, but there's one problem - long function names.
I find it hard to write code with 7-character identifiers... Is this
fixed in 1.40? Also, will it handle LARGE libraries (ie Game Workbench,
etc.)? Currently, I'm using Sozobon 2.0 (and watching both the compiler
and my programs crash a lot), mainly because of the long identifiers...

The method they used should be possible to implement without too much
bloodshed, if you haven't yet, and it would be a great boon to mankind.

Much thanks...

There is only one excellent quality book that I am aware of that contains almost all, if not all, information you might be interested in. It is called the "Atari Profibuch ST-STE-TT", however if you don't read german you can obtain the Atari developers package which contains three binders of information about the Atari series.

There is another option, you can call Motorola and the other appropriate parties involved, and obtain the technical books. Motorola will be more than happy to assist you and send you the book/documents. The 'special' chip pin-outs, timing diagrams and such will be only available from Atari Corporation.

Sincerely,
Mark K.

it is possible. use vex_motv to replace the mouse movement vector. i wrote something a long time ago to do this. the application involved dragging the mouse in a windo to mark a region. when u got to the edge of the work area, the next "page" of data was displayed an the mouse jumped to the other side. worked well. felt well.

if u want i will post some code if i can find it...

whatever method is selected, it should not break existing executables.
and it should be friendly to existing shells (bash, ash, tcsh, ksh, gulam,
etc, most of which are compiled with gcc and MiNT). i don't think the \1
idea will work in this context. the method should also be friendly to
library process creation routines (system, exec*, spawn*, etc).

from what i see, the only method that is guaranteed not to break anything
is the second env variable, however messy it is. it could be added just
before ARGV. eliminating a single space as a valid arg is unacceptable.
there are times that i need to do: echo -n " ". i am not sure what impact
using \n would have either. can shells pass a newline in an arg list?
i know this is possible (tcsh under unix):

```
% echo "hello\
? world
hello
world
%
```

let's look before we leap. there is no need to rush this...

->" However, I have had a similar problem, but from Hard disk, and it has
->"never been serious enough to worry about it (so I haven't) but I wonder if
->"anyone else has had this happen. Almost every time I boot my computer (NOTE:
->"this is _not_ every time), it will bomb with a couple of bombs (don't remembe
->"how many), then it will restart and load just fine.

I have a Supra SCSI interface with 4 40Mb hard drives. To recognize all
of the drives, I have to turn the drives on, let them come up to speed,
and the turn them off and on again.

And as for my STe, about 10% of the time it bombs upon boot. It is about
a year and a half old, and has always done this. I have had two previous
ST computers that also would randomly bomb upon bootup.

I finally decided that this is just one of the joys of Atari computing!
Once the machine is up and running, it takes a buggy program to take
it down!

> it was intended for.

Why not use the ARGV variable itself to do this? I.e. for
cmd '' foo.c '' bar.c
the environment would look like:
ARGV=1,3\0cmd\0foo.c\0bar.c\0\0

The current standard doesn't specify what should come after the ARGV= string. This is because MWC uses that for file information; but since MWC is no longer supported, I don't think this should be a big problem. (Does anyone know what MWC compiled programs will do if they encounter an illegal ARGV= string?)

> - Using an escape character or sequence such as \1 to indicate an empty arg.
> This is workable, and very easy to implement. The drawback is that it
> may confuse current applications that don't expect \1 chars in args.

I think an escape sequence is also a good idea, and it definitely should be a character that is highly unlikely to appear in "normal" applications; indeed, I would suggest something like 0xff rather than \001, just because characters from 0-127 tend to show up much more often. Whitespace characters would, I think, be a very bad choice, simply because they already appear regularly in arguments.

My preference would probably be for a highly unusual escape character, but if we can figure out an easy way to use the ARGV= string itself I'd vote for that as well. I heartily agree with Bill R. that we should *not* rush into establishing a standard!

Did you buy this new or used? If it's an older MSTE, it's going to need some changes made to it by your dealer, including a new PAL, a jumper, and rerouting the power cables to the hard drive.

The Mega STE I used to have had this problem, and it even needed an Ajax chip for the TT (supposedly, there's two part numbers for the Ajax, one for the MSTE, one for the TT). The reason we put in the TT's Ajax is that large files over 100K or so would result in Data on Drive x: errors, whereas smaller files would not.

2978. G++ Environment question

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-01 23:35:08 UTC
From: cbbrowne@csi.uottawa.ca
Message-ID: <1992Aug1.233508.3984@csi.uottawa.ca>
Source record: 43329

I've been using GCC for a while (and am very happy with it!) but have
been having a bit of a problem lately. I want to start using some of
those spiffy new C++ features, and gradually migrate towards C++.

Unfortunately, I can't get it to compile code :-(.

The reasons were a total mystery until today, when I finally decided
to "solve" the problem. I got PART of the answer...

What seems to happen is that gcc.ttp can't find gcc-cc1+.ttp. I ran
gcc.ttp with the -v option, so that it verbosely prints out all of the
commands that it runs.

When I compile standard C, the relevant command is as follows:

```
d:\gnu\bin\gcc-cc1.ttp f:/tmp/cc100000.i -quiet -dumpbase testnsim.c
-c -o f:/tmp/cc100000.s
```

This works fine.

When I change the file to testnsim.cc, the equivalent winds up being:

```
cc1plus f:/tmp/cc100000.i -quiet -dumpbase testnsim.c
-c -o f:/tmp/cc100000.s
```

which is fairly obviously incorrect. The initial string OUGHT to be
"d:\gnu\bin\gcc-cc1+.ttp", rather than "cc1plus". I've a nagging
suspicion that I ought to have some environment variable set for this
to work right.

I tried using "setenv GXXEXEC d:\gnu\bin\gcc-", as an analogue to the
gcc "GCCEXEC". This didn't improve the behaviour, alas!

Is there anything obvious that I'm missing here?

Here's the relevant part of the environment variable setup...

```
# Chris's MUPFEL.MUP
# Environment variables for GNU C
setenv GCCEXEC d:\gnu\bin\gcc-
setenv GNULIB d:\gnu\lib
setenv GNUINC d:\gnu\include
setenv GXXINC d:\gnu\include\g++
setenv CC gcc
```

As it was pointed several times: won't work, unless you find a
verification method.

>eliminating a single space as a valid arg is unacceptable.

Why? That should only be done if the startup code identifies the
ARGV contents as 'revision 2 type'.

Applications shouldn't change vex_motv. This will produce a lot of
problems with concurrently running accessories or applications (Mag!X,
MultiGEM, MultiTOS).

Anyway: I still don't like the idea of warping the mouse cursor, BUT
I am still sure that it can be done with appl_tplay. Whoever wanted
to know that: please tell us what you did try and in what way it didn't
work.

This will break *all* properly written programs. The ARGV standard
says that it is *really* ARGV=<anystring>, and all programs written
with this text in mind should check for the = sign (and many actually
do it :-)

Besides: you can't pass a double \0 *in* the environment: GEMDOS
copies the environment only upto the first double \0\0 in the
environment. This will break your second proposal, too.

I would suggest that everybody doing proposals about extending
ARGV should carefully reread the original ARGV documentation. Thanks.

> it was intended for.

I don't believe that we'll find a place to do that. For obvious reasons,
it can't be in the environment. So it has to be somewhere else in the
information passed by Pexec(). Where????

Obviously we'll have to use something like an escape mechanism (or
the 'blank-adding'). We should look for

- a clean definition: new programs should be able to tell whether they
have been launched using ARGV or ARGV2. I think that we'll have
to use the contents of ARGV= itself.

- backward compatibility: old programs (by definition) never have been
able to receive empty arguments, so passing something 'strange' to them
doesn't make it worse.

The question is: is there a way to put something in ARGV= without
breaking MWC programs. If not, do we care? I'd like to see something
flexible, so that later we'll be able to pass more information there.

Example:

ARGV=<field name>=<value>,...

with escape mechanisms for '=' and ',' and one field definition defined
for the ARGV revision level.

or perhaps something with fixed field format without the need for quoting:

ARGV=<variable>,...

with:

<variable> := <field name><field length>':'<contents>
<field name> := a fixed length identifier (4 characters?)
<field length> := ASCII field length
<contens> := the contents of the field

For the start, this would look like:

ARGV=VERS1:2

with fieldname VERS (ARGV version), field length 1 and field contents
'2'.

Whatever we do, we should try to minimize the work needed for parsing.

> Use the ARGV= itself...since MWC is no longer supported

Well, it may be unsupported, but I don't think that means it's unused.
Even if nobody today was using MWC at all, there are still a lot of old
programs out there that'll be with us for years. So, the functional question
has to be: what will one of these programs do if it finds an unexpected
value in the ARGV variable? If the program will fail, or will behave in
noticibly (to the user) unexpected ways, we'd better not even consider it.

> 0x01 versus 0xFF as the escape

Is 0xFF a character in any of the European or other character sets supported
by the ST? I picked 0x01 because it's a non-printing character in every
language based on the ascii charset. I have no idea what happens with chars
over 0x7F, other than the nebulous idea that some of them are used in other
languages to represent national alphabets. (I'm soon gonna be coding up a
locale.h and setlocale() and stuff for HSC. I'll bet I know more about
international charset issues by time I'm done with that! ::grin::)

2984. Re: ST Hard Drives

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-02 19:00:19 UTC
From: ilepore@nyx.cs.du.edu
Message-ID: <1992Aug2.190019.4791@mnemosyne.cs.du.edu>
Source record: 43330

Organization: Nyx, Public Access Unix at U. of Denver Math/CS dept.
X-Disclaimer: Nyx is a public access Unix system run by the University
of Denver for the Denver community. The University has neither
control over nor responsibility for the opinions of users.

I don't know if it's possible to hook IDE drives to an ST (someone whould
have to make an adapter; I've never heard of one).

But, you can get medium/small SCSI drives from Dirt Cheap Drives in Texas.
1-800-872-6007, 1110 NASA Road One, Suite 304, Nassau Bay TX, 77058.
(I've bought drives from there and had no problem with them; they ship fast.)

An ad from an old Computer Shopper lists ST157N 28ms 49mb 3.5" $239,
ST296N 28ms 85mb HH $269, ST1096N 20ms 84mb 3.5" $279. (All segate).
For Conner drives, they have CP3040 25ms 42mb 3.5" $235, CP30060 18ms
64mb 3.5" $299, CP30080 18ms 84mb 3.5" $349.

There's others in the 40-80mb range too, just call and ask. I got an
ST1096N from them, and I love it, it's fast and they had (at the time) the
best price on it.

(All drives above are SCSI; most come in MFM/RLL (ST506 interface) and in
IDE flavors as well.)

> whatever method is choosen, it should not break existing executables
> I don't think \1 will work in this context...
> the only method g'teed not to break anything is the 2nd env variable

Last point first: adding a 2nd env var requires a second validation of
some sort, so that if the args get passed through an unaware program to a
child that is aware of the extension, the child has some way of determining
that the 2nd env var was destined for it, and not its unaware parent. I
haven't seen any proposal yet on how this validation might be done. (IE,
this needs to be something that has the same validating effect as putting
0x7F in the length byte of the command tail, but it has to be different,
since it's validating something different than the plain ARGV.)

Now, on to Not Breaking Existing Programs: this seems to me to be a
Non Issue. Right now, there is no way to pass a null arg to a program
at all. No matter what method we cook up for doing it, an older program
IS GOING TO MISBEHAVE if you pass it a null arg, because it doesn't contain
code of any sort to recognize and handle it. It's a bit disingenuous to
claim that a \1 will confuse an older program if it's used as a marker
for a null arg in that spot. What if we use a 2nd env var instead? Well,
that env var will say "the 3rd arg is null", implying that what appears
to be the 3rd arg in the ARGV area is really the 4th, and so on. Now,
given an older program that doesn't recognize this new env var, it's going
to mistake the 4th arg for the 3rd, and be off-by-one on args beyond that
point. Please convince me that this won't lead to worse problems than
having a \1 as an arg!

Let's say we have an older application that takes parms like this:

foo some_string outfilename [optional_infilename]

You invoke it as 'foo "" tempfile.out important.in', so the new scheme
(which foo is blind to, having been compiled years ago) passes:

NULLARGV=1\0ARGV=\0foo\0tempfile.out\0important.in\0\0

The first parm is supposed to be empty, but foo doesn't know that, so it
takes "tempfile.out" to be some_string, and it takes "important.in" to be
the output file, and thus is wipes out your important input data when it runs.

To reiterate the basic point: no program is currently able to handle null
args, because no scheme currently exists to pass them. Thus, anything we

do will cause some program to misbehave in some way if you pass a null arg to it using the standard we cook up here. Thus, we don't need to be concerned whether our new scheme would break existing programs if a null arg is passed to them; it always will. What we need to be careful of is that the new scheme doesn't break existing programs when no null args are passed.

2986. MiNT 0.95 now available

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-02 23:15:39 UTC
From: 7103_2622@uwovax.uwo.ca
Message-ID: <1992Aug2.191539.1@uwovax.uwo.ca>
Source record: 43336
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

MiNT 0.95 is now available for anonymous FTP from atari.archive.umich.edu.
The files are:

mint095b.zoo -- executables for MiNT
mint095s.zoo -- MiNT source code
mntman95.zoo -- MiNT programmer's manual (nroff man pages)
mntutl95.zoo -- various utilities for use with MiNT; these haven't
changed much since 0.93.

Along with the MiNT executables is provided a beta version of TOSWIN,
a really nifty (well, I think so :-)) new window manager that can work
as a .ACC. Unlike the old BGACC, this one supports arbitrary GDOS fonts
(including proportional fonts!), scrollback (like xterm), and allows
for dynamic resizing of windows.

Please read the "readme.1st" file that comes with MiNT. The MiNT installation
procedure has changed somewhat with every version. The basic idea is still
the same (put mint.prg in your AUTO folder), but there are now more options:
for example, mint.prg no longer has to be the last thing in the AUTO folder,
and if you hold down the right shift key while booting MiNT will ask you
if you want to start it.

There are also lots of new features in 0.95, including better terminal
support and a shared memory file system. See the "readme.new" file that
comes with MiNT for more details.

I have the ST1096N as well and I'm very satisfied with it. I mounted it inside my MEGA ST2 using ICD's AdSCSI Micro ST host adapter. It was the perfect solution as I didn't have the room for an external drive. It was so simple to install as well. Lift the lid, bolt the mounting bracket to the motherboard, add the drive, connect the power and DMA cable, and close the lid. The installation was so easy I think Atari actually considered an internal drive kit while developing the MEGA ST.

I can't imagine living without the hard drive now! I Should have installed a year before I actually did. My only problem is that I'm running out of room!

Date: 1992-08-03 00:45:29 UTC
From: rosenkra@convex.com
Message-ID: <1992Aug03.004529.5171@convex.com>
Source record: 43335

the fact that i can pass a newline, tab, bell, and probably other "non-printing" chars means that someone could conceivably want to also pass a \01 as a valid arg. i am not saying this is likely. i am saying the probability is non-zero. i agree with you that since ARGV can't handle a null arg now, that there is nothing to break (except a single aspect of grep which has a work-around for this anyway). i don't think it is wise, however, to limit a particular behavior simply because it is not used today. that is what TOS is all about :-(. i just don't want to have to recompile 200+ programs when a new shell comes out with a new method for this or keep maintaining my own version of the shell (which wastes communal energy). since it is unlikely that i will ever use anything but tcsh under MiNT, and since ers is the "de facto" maintainer of tcsh (and i totally trust eric to do the right thing), i suppose this is not as much of a problem as i make it out to be.

i am also not sure why this info can't be tacked on after the \0\0 in the ARGV string. i know Pexec stops parsing after the \0\0, but a shell interpreting args for Pexec is not subject to that restriction. it could also propagate the extra info into the env of the Pexec'ed process. i realize that this would not work for the desktop (which does not grok ARGV anyway, at least TOS 1.2's doesn't).

finally, how many things would actually benefit from some new scheme? do we really have a problem here? (if it's not broken too bad, don't fix it) i write/manage lots of code and lots of scripts and have (so far) never had a real need to pass a null arg. there are always workarounds. i don't like tools with "positional" args. to me this is a poor design. the only exceptions are things like mv and cp (in which case the last arg is the target). or possibly things which have optional targets (eg, cmd [in [out]]). this, again, is weak since with a decent shell, "<" and ">" can be used. as for grep, awk, etc that do have positional args, these should be well understood by now. these sorts of behavior are ingrained in unix to a point that users generally know intuitively what to expect. however this is philosophical (and perhaps pedantic). perhaps a survey of all known progs and their args should be made before ARGV is changed to assess the impact a change would have. does anyone know what POSIX.2 has to say about this? and what about "new" execution modes for Pexec in MiNT, say?

let's keep this topic going. the fact that we are discussing this is infinitely better than just doing something without other opinions. if we reach a "lesser of evils" consensus, this would be great. all of the restrictions with the method should be defined as well as the impact it would have on lots of existing stuff....

this will break every current shell compiled with gcc (bash, ash, ksh, tcsh)
as well as things like echo, grep, etc. with the multitude of versions of
shell utilities, different update levels of libraries people use to develop
these tools, etc i suspect this would be a management nightmare. you'd
have to make sure that every program is compatible with your shell (with the
current ARGV, i can run .ttp's that i compiled 5 years ago). for
me this means recompiling 100-200 programs (or worse: find every one in
which a string of one or more blanks (ascii 040) is valid and just recompile
(or port and recompile) those, assuming i had src of course). there may
actually not be that many programs that actually have a problem, so i
suggest we consider that first before we break dozens (scores?) of others.
first let's find out how bad this "problem" is before we fix it. i suggest
we do nothing until we can answer this rather basic question first. since
i consider myself a fairly proficient unix programmer and in the course of
any day will use perhaps 50 different programs and have never had a problem
with this, i wonder what the fuss really is all about. the grep example that
started this has a workaround, i think. if it is just a typing convenience
thing, use an alias or script. or somewhat worse, develop another tool. or
(again somewhat worse) perhaps develop a superset capability as in
"grep +default_pattern file". i suspect if you suggest this to GNU/FSF,
they'd say "your shell/environment is broken. fix it, not grep."

oh, i also assume we are talking purely about command shells and not the
desktop or desktop replacements, too. since i don't use desktops, i can't
talk about the impact there (end of disclaimer :-).

>Of course, this new method *could* be signaled by a string in the ARGV
>value (which is normally unused). However, I am not sure whether that will
>break existing programs (MWC?).

as much as we'd like to say forget MWC since it is not supported, i don't
know if we should go so far as to cause all the people who spent $$$ on it
to abandon something that otherwise works well. in this case the cost for
progress is real currency. with GNU and other "free" stuff, this is not a
big deal.

you could just as easily propose that the first/last arg in ARGV string is
used only for positional info. this, of course, would break everything, too
(literally everything, not just occasional things). i think this is similar

to fortran's calling convention (it pushes the number of args on the call stack). as Ian (correctly) points out, using \1 in null args does not really break anything except whatever programs (if any) that might expect a real arg with \1 in it. this does sound like a better idea with the one exception i cited. note that i can think of a use for a \1 in the command line (eg a binary patching program) tho i am not sure how to get it there (^A?). i can also think of a workaround for this, too (use ascii and convert).

thus i think the basic trade-off is: what is the impact of leaving things alone (what will not work correctly) vs what is the impact of the \1 thing (how many things will it break)?

depends on your env. if you can link with a decent C library,
then installing our own handler using signal(SIGINT, myhandler)
is probably the easiest. note that under TOS the handler will be
invoked only on the next console i/o. under MiNT it will be "instantaneous".

if not, you have to detect ^C at the console yourself. under
MiNT you can install your own handler using <mintbind.h>

2993. pagestream from floppy disk?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-03 05:29:59 UTC
From: 10616330@eng2.eng.monash.edu.au
Message-ID: <10616330.1.712819799@eng2.eng.monash.edu.au>
Source record: 43339

I am currently running Pagestream v2.1 on my 1040ST with one floppy drive, no hard disk, mono monitor and Epson LQ 100 printer.

My problem is that the program crashes every now and then for no apparent reason, particularly when trying to change the font of the entire text, even when there is very little text entered.

The program also crashes (sometimes with 6 bombs) if, after printing a document, you try to print another, without exiting pagestream and reloading. After the first print, the screen is corrupted, with the left hand half of the menu being unreadable, but subsequent screen redraws will recover the lost screen info.

The problem seems to be with a lack of memory, however no-one seems to know any way to stop this happening.

Any help on this problem would be great. I also know some other tricks with pagestream for any novice users.

Big Stu

>interpreting args for Pexec is not subject to that restriction. it could
>also propagate the extra info into the env of the Pexec'ed process.
>i realize that this would not work for the desktop (which does not grok
>ARGV anyway, at least TOS 1.2's doesn't).

No. Pexec() creates a *copy* of the environment. That's the whole point:
the environment memory is a *copy* of the original environment, and the
memory belongs to the child. And this copy ends at \0\0.

I have a pair of 'non-StereoTek' LCD glasses that I plan to connect
to my ST. What I am looking for is info about how the StereoTek glasses
were connected because I want my glasses to be 'StereoTek compatible' after
I get them working (just in case I ever run across any software that made
use of them). I also plan on writing some software to use them and I would
like people that have the StereoTek glasses to be able to use my software
too.

Thanks!

ok, i see. is this also the case if u pass a null for env in Pexec? what
exactly does it mean for the child to "inherit" the parent's env? is
this the copy thing? also, why couldn't the parent provide its own
env directly to the child, containing stuff after the \0\0? as i read
the Pexec docs, the parent can provide the env with a non-null env.
are u saying the child will then copy this, no matter what? so there
is duplication? is there no way to share this env without a copy? i know
it is possible since i have the src to MiNT... :-)

of Denver for the Denver community. The University has neither
control over nor responsibility for the opinions of users.

Well, it looks like every proposal so far has some glitch to it. What's
worse, it looks like the glitches may be fatal in all except the \1 scheme,
because they either break existing programs, or require additional validition
to prevent passthrough-unaware-parent problems.

The glitch with the \1 scheme is minor, I think, and the fix is easy. But,
the first question has to be: is it really a glitch? If anyone ever wanted
to pass a \1 as the first character in an argument that isn't null, then the
\1 escape mechanism will interfere with that. But, do we want to define a
standard that allows passing arbitrary binary data via the command line
args? I tend to think that's a Bad Thing, but that's a purely personal
opinion.

Here's a couple proposals that should work if the world decides that we
really have to be able to pass binary data via args:

Idea 1: \1 is a generalized escape mechanism for binary data in args.
The sequence \1\1 is translated to \1.
The sequence \1\2 is translated to \0.

Idea 2: \1 is the specific escape for a null arg.
\2 is an escape that says "this arg contains binary data in an
application-specific format."

I don't like idea 1 that much, because it puts a bigger burden on the ARGV
parsing in the child program; it will have to scan every char of every arg
looking for escape sequences. But, it does allow arbitrary binary values
to be passed with a minimum of hassle.

Idea 2 actually has some merit, to my way of thinking. It keeps a child's
ARGV parsing simple, because only the first char of each arg has to be
examined, and the standard parser (your runtime startup) only has to deal
with the \1 escape; a \2-escaped arg is passed along to the ap in argv[]
just like any other. If the application is aware of \2 escapes, it handles
them itself. The only advantage I can see to this is that it would allow
for a suite of tightly-coupled programs making up an application to pass
data among themselves in a format that only they need to be aware of, and
they can use a format that makes the most sense to them.

Oh hey -- here's an even simpler idea that just occurred to me: use \1
as the escape. If the arg in ARGV is \1\0 that's a null arg. If it's \1\1
that means the first char of the arg is really a \1, and the rest of the

arg is just plain old data. This doesn't allow for arbitrary binary data
though, in that it doesn't sanction a method of passing/escaping a \0 char.

Stu--

The only way you're going to solve your out of memory problems with Pagestream is to add more memory. If I recall correctly, Soft-Logik doesn't recommend anything LESS than a system with 2megs of RAM and at least 2 floppies if no hard drive. I'd suggest your going back to v. 1.8 if you can, until you upgrade your system.

> [statements & questions concerning what Pexec() does with the env]

When GEMDOS creates a new process via Pexec(), it creates an environment data area for the process. If the Pexec() call contained a non-NULL env pointer, it assumes that pointer points to a string area formatted as string\0string\0string\0\0 -- it doesn't really care what's there, it only knows that a \0\0 terminates the data. Since the new process created via Pexec() gets a copy of the data, and GEMDOS does the copying by cruising until it sees \0\0, there's no way to ever pass data beyond a \0\0 sequence to a child program via the env.

The fact that GEMDOS creates a copy of the environment data (rather than just passing the pointer specified in the Pexec()) is an important one. A child process should not be able to modify its parent's data (at least, not without specific permission from the parent). A process is allowed to modify the env data it receives, so it has to receive a copy of the env, not a pointer to the parent's copy.

When you pass a NULL env pointer in Pexec(), the only difference is that GEMDOS retrieves your env data pointer from your basepage, and uses that as the source when copying the data for the child being created. This is really just a shorthand notation for you, it means you don't have to code something like Pexec(0, path, cmdline, __base->p_env); by coding NULL, you're asking GEMDOS to use __base->env for the source of the env data. Since __base->p_env points to the env data you receive from your parent, this is referred to as 'inheriting' the environment. But, you still inherit only a copy of the environment, and the copying stops at the first \0\0 encountered.

> On the problem of passing empty/null arguments via ARGV, we've had so far:

Just to add one more proposal (in fact it is an old one):

- Ever heard about xArg? The xArg-extended argument passing method
of Dale Schumacher never had problems with empty arguments:
1. The xArg-struct contains argc, so the correct count of
arguments is available.
2. Since the contents of the xArg-struct are not copied by TOS,
it won't choke on double zeros.

I know that some people will repeat the arguments about xArg being unsafe in a multitasking environment, since the struct resides in the parents address-space. But is this the only way to implement it? - No! If the OS (eg. MiNT) knows about the xArg passing, it could copy the contents of the whole struct for the new process.

Bollocks! The only effect of the above EXCELLENT proposal is that old
children will get null arguments passed as " " (which is no worse than
not being passed them at all!), and will get " " passed as " ", etc.
So what. How often will this occur???? Even if it does, it's just a
simple matter of the user saying "oh well, XXX was compiled with the
old ARGV convention, I'll just use on less space in that argument, until
I get a recompiled version" - except when she wanted to pass a null
argument, but that wasn't possible before anyway. And remember, it is
a *change* to grep source code that is required, just the crt0.o it was
linked with.

3005. appl_tplay() (Was: Gem program control of mouse)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-04 08:22:30 UTC
From: reeuwijk@dutentb.et.tudelft.nl
Message-ID: <1992Aug04.082230.9506@donau.et.tudelft.nl>
Source record: 43358

For those people wondering how you can get appl_tplay() to work:

The secret is that the docs, even the official Atari docs, are *wrong*.
According to the docs you need a packet of 3 ints (6 bytes)
for a mouse movement event: 1 int for the opcode and 2 ints for the
coordinates. In reality you need 4 ints (8 bytes) because you must
first send a 0 word (or the opcode is a long word, which is equivalent).

However, according to some people this differs between TOS versions.

In case you are wondering: I use this function to track the position
of a pointer on a digitizing tablet.

> for dynamic resizing of windows.

Yes, I agree, TOSWIN is really neat stuff. But there's still one nasty
incompatibility with NVDI (2.0.3), the same as in BGACC: If you have NVDI
installed, you have to set "alias precmd 'echotc vi' and sacrifice
your cursor, because otherwise every second or third keypress only
produces a black cursor box in the command line, covering the letters.
Thus, command line editing in tcsh is no more fun, editing in vi or
emacs, too.

I don't want to miss NVDI - screen output performance would be lousy
without. Any suggestions what to do?

Regards,
Markus.

I also would like to second this oppinion. Following is therefore a solution which is not completely general, but should solve a lot of applications that I can think of.

I came into the middle of the discussion, so I'm not aware what exactly Ian Lepore needs this for, but it occurs to me that it most be possible to use the commando tail for the purpose. It has a limited length, but it still should be able to handle over 100 empty args, providing a lot but not infinite functionality.

One way to make this operational, would be to define a new magic tail-length, like length 127 meaning ARGV is employed. Say this value is 126 (which should be an illegal length anyway). Then the interpretation of the tail could be that the characters of the tail would hold either the index of an empty arg or 0. This leaves room for some 125 (ca.) empty args positioned freely among the first 255 arguments (excluding argv[0], but that should be no problem).

This would have implications for the ARGV scheme, since this would expect 127 as length. An alternative to changing ARGV would then be to include the next tail char, saying that if tail[0]==127 then we are using ARGV and if tail[1]==255 (or some other appropriate value then we are using ARG0 (just a sugestion for the name).

Hello,

I've been trying the following:

```
#define in_line_procedure (arg, arg2) {\
arg=arg2+arg2;\
#ifdef SPECIAL_CONDITION
arg-=1;\
#endif
}
```

But, this don't seems to be proper C. I think that the problem is that I want the #define spread over several lines, but that the #ifdef must be at the beginning of a REALLY new line. Must I live without this type of programming or is there any solution?

Please email: bert@cs.vu.nl

Thanks, Bert.

weird thing. I has similar problems (massive reset series after some minutes
or hours of use) and the reason was a bad power connector. You should check
the voltage when computer starts to reset. The power led is no solution as
you won't see the small voltage breakdowns.

Your problem could also be caused by software. Check your accs and auto folder
programs if the computer works fine when booted without a disk...

The question of how important the empty argument issue is can be
answered with VERY. I discussed this with a colleague at work who
knows more about the subtilties of POSIX.1, .2, and unix kernels than
I.

Any utility that takes strings, other than filenames, must be
able to handle arbitrarily long strings (>= 0). The failure
of the utility to handle an empty string would be a serious
bug. The failure of the kernel or shell to pass arbitrarily
long strings would be a major design flaw.

The reason that we have not come across this problem is because it is
only now with replacement OSes like MINIX or MINT that allow us to be
more unix like that we are writing more portable unix-like utilities.
Also the fact that we may not use it in interactive use does not mean
it is not get used in csh, ksh, or rc scripts, of which 'test' is
probably the most common utility that empty strings are passed to.

Not sure about the megafile... but
Inside the sh-204 is a "atari host adapter"
a somewhat lobotomized adaptec 4000a
and an mfm seagate ST-225 mechanism.
(3 pieces, not incl PS and wire)

So... If you wish to replace the st-225, you'll need a larger MFM drive.
If you replace the combo of the adeptec 4000a and st-225 you'll
need a SCSI hard disk.

My experiences have not gon well with the Atari adapter, except for
once when I tried my ICD utilities on it. Then it would format and partition
odd size drives. I recon the NEW atari utilities are better... Sure hope
so!

From: ant@mks.com
Message-ID: <1992Aug4.153845.13383@mks.com>
Source record: 43365

The use of \1 escape to denote empty strings would cause serious
problems. Csh, ksh, and rc shells all have the ability of passing
octal escape sequences in strings.

An example is the SCCS file format for history files which are text
files. ^A is used as a character that denotes the start of SCCS
control lines.

It might be the case that I wish to grep for all such lines in a file.

grep '\001' *

Or translate them from ^A to caret

tr '\001' '^' <file >output

The \1 format would break both these instances. The fact that a lot of
people don't use octal escapes in their parameters does not mean they
might not want to in the future or that some people already do.

The \1 format would change one problem into another which is no good.

>#endif
> }
```

Remember that '#...' directives are dealt with preprocessor which is doing, more or less, a text substitution before compiler will see any of this stuff. So yes, the above is obviously incorrect. If your compiler allows it run preprocessor only and look at results to see clearly why. I you need something like that badly have two separate defines. One when SPECIAL_CONDITION is in force and the other one for the opposite case.

Message-ID: <13984@mindlink.bc.ca>
Source record: 43362

I have an old (1986) sc1224 colour monitor. A couple
of days ago it quit displaying anything. When it is
turned on it remains black. The sound still works. The
red light on the front still lights. When I turn it off
the green lines that flash and shrink to the center still
flash and shrink to the center.
It is connected to an old 520 with 2.5 meg memory
upgrade.
Any ideas about what is going on??Any help or info
would be greatly appreciated!!

3017. Help with Megafile 30, HDX Software

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-04 17:30:48 UTC
From: bq035@cleveland.Freenet.Edu
Message-ID: <1992Aug4.173048.11173@usenet.ins.cwru.edu>
Source record: 43363

I've been helping out a friend of mine with some problems with their Atari, problems which are universally focussed on their 3-year old Megafile 30. Whenever it crashes (often), I try to reformat it. Most of the times when I format it, The formatting software (I've used HDX 3 and 5) locks up.
Is there any way to low-level format this disk? Are there any heavy-duty diagnostic tools which I can use on it? The HDX software is generally a bad trip, as I get no errors, just a locking up. I would appreciate any infos.

3018. checking for stack overflow

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-04 17:53:49 UTC
From: scoile@gmuvax2.gmu.edu
Message-ID: <1992Aug4.175349.7069@gmuvax2.gmu.edu>
Source record: 43367
Cross-posted to: comp.programming,comp.sys.atari.st.tech,comp.sys.m68k

I've just recently begun learning and programming in assembly (68000 on an Atari ST) and have started wondering how other programmers out there deal with stack management.

A lot of the programming examples I've seen make free use of the stack, without checking for stack over/under-flow. Is this safe? Is there any way to monitor the size of the stack, without causing program size to explode? Is it safe to use the stack as work space? I guess I've always thought of the stack as just a way to pass arguments to subprograms.

Any assistance would be greatly appreciated.

3019. A new GNU Make 3.62

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-04 19:38:01 UTC
From: chu@acsu.buffalo.edu
Message-ID: <BsH57E.9tB@acsu.buffalo.edu>
Source record: 43366

Frank Ridderbusch asked me to put his new port of GNU Make 3.62 into atari.archive.umich.edu which I have just done. Currently, it is in the new directory (although I just received a note from Jeff Weiner so it might get moved to the proper place soon). The name is gmake362.zoo

Attached below is the readme.st file from the archive. Thanks Frank for the new make!!!!

john
chu@acsu.buffalo.edu

-------------------------readme.st--
* Mon Jul 27 22:02:50 1992

The first archive of GNU make 3.62, which I sent to the atari@archive.umich.edu had some code in it to make the rules for checking out RCS file work. This code seemed to work only on my system and was basically wrong anyway. Since Stefan Neuhaus ported `ash' to the ST, this code is additionally obsolete. (`ash' is the compatible replacement for the Bourne Shell in the current BSD unix distribution). This make executable is now compiled with GNU-C 2.2.2 and Bammi's libs and header at patchlevel 82.

The supplied diffs are relative to the GNU-make 3.62 distribution from prep.ai.mit.edu.

Note:
=====
If you want to use this make in conjunction with `ash' or any other shell, you have to set the make variable `SHELL' explicitly to your desired shell. Having simply set the variable in the environment is not enough since GNU-make resets SHELL for security reasons to `/bin/sh'. Therefore you have to invoke make either like this:

make SHELL=d:/mint/bin/sh.ttp

This sets SHELL to the specified shell (note the `.ttp' extension). Another way is to edit your makefile and include the following line:

SHELL=d:/mint/bin/sh.ttp

Again with the `.ttp' extension.

* Thu Jan 2 19:44:08 1992

This is a port of GNU make 3.62 to the ST. The work on my part is, that I carried the changes from Frank Celler and J.R.Bammi from earlier ports of GNU make over to 3.62. The executable is currently

compiled with J.R.Bammi's ST libs and headers at patchlevel 74. I
reenabled some code from Bammi to hash only the 8.3 part of a file
name (see the file dir.c). Without this GNU make wouldn't remake
targets with names, which were longer than the 8.3 notation. If you
might be working on a file system, which allows more than 8.3
character file names (minixfs under MiNT), you should disable the
atarist code in dir.c and use the original.

See also the readme from Frank Celler, which is below my signature.

These are the atari-diffs for GNU make 3.60. I am using the "ksh" with
UNIXMODE, which allows long and upper/lowercase filenames, so there is
no filename reduction to 8.3 filenames. The shell-escap however is changed
from '\\' to '@'. If your shell does not support "||" you should edit
the default dependency in "default.c". "make" must be compiled with the new
"crt0.c" from J.Bammi in order to allow recursive makes.

3020. Transfer Protocols

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-04 21:32:38 UTC
From: markjl@pub2.bu.edu
Message-ID: <92830@bu.edu>
Source record: 43368

Hello there,
I am looking for technical specifications for any of the following
file transfer protocols:

- Xmodem (Checksum and CRC)
- Ymodem (1K block, Batch, and Ymodem-G)
- Fmodem (4K block Ymodem?)
- Zmodem

Additionally, but not necessarily, it would be nice to know more about:

- Cmodem (Jerry Horanoff's protocol, maker of Carina BBS)
- CIS Quick B
- Kermit

I just wanted to get up to a thorough understanding of what I use from
day to day. I never really understood things past Ymodem batch, like
what exactly is a windowed file transfer (a transfer which does not have
to wait for ACK or checksum or CRC responses before sending the next
block?) and how is it implimented? And how is a CRC calculated?

On a related note, I wondered if anybody out there could explain the
implimentation of modem hardware data compression, such as V.42 bis,
and modem hardware error correction, such as MNP 5.

Any and all replies, documents, etc. are appreciated. Life is an educa-
tion that never ends. Please email me at: markjl@acs.bu.edu.usa.

Thanks! - Mark J. Lavi (at Boston University)

P.S. Of course, you know eventually, a follow up message of inquiry will
---- ask for understanding of *.lzh, *.arc, *.zoo, *.zip compression!

> Applications shouldn't change vex_motv. This will produce a lot of
> problems with concurrently running accessories or applications (Mag!X,
> MultiGEM, MultiTOS).

Say what? Where does it say that? The way I read the VDI manual,
vex_motv() is specifically designed so that applications can use it without
interfering with other parts of the system. (IE, vex_motv() is the
preferred way to steal the mouse, as opposed to Line-A or other deeper
hook points.)

If Atari has changed or restricted use of vex_mottv(), I'd be interested in
knowing where it's documented. (I just got a complete new set of devkit
docs, so if they've done it, I should have it somewhere, but I can't find it.)

Even if there is a restriction on vex_motv(), it should be safe to use
inside a wind_update(BEG_MCTRL) / END_MCTRL block.

> ... I don't know what Ian Lepore needs this for ...

Actually, I don't personally need it at all. Someone else expressed a
need for it, and my interest is as a library implementor. It seems to be
a reasonable request -- other systems allow for passing null args, and the
ST shouldn't be locked out of compatibility in this respect.

> ... use the command tail to indicate the position of null args ...

Fails the test of "will it break existing applications".

>
> #define in_line_procedure (arg, arg2) {\
> arg=arg2+arg2;\
> #ifdef SPECIAL_CONDITION
> arg-=1;\
> #endif
> }

Remember that line-splicing happens before preprocessing. What you've
really done is, in effect:

#define x(a,a2) {a=a2+a2; #ifdef SPECIAL a-=1; #endif }

And when you look at it that way, it's immediately obvious why you can't
do it. Here's a way to do it that's only semi-awful:

```
#ifdef SPECIAL_CONDITION
#define SPECIAL_ARG arg-=1;
#else
#define SPECIAL_ARG
#endif

#define in_line_procedure(arg, arg2) { \
arg=arg2+arg2; \
SPECIAL_ARG \
}
```

You might want to think up a better name than SPECIAL_ARG, but that
should work.

3024. Re: checking for stack overflow

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-04 22:20:23 UTC
From: ilepore@nyx.cs.du.edu
Message-ID: <1992Aug4.222023.5442@mnemosyne.cs.du.edu>
Source record: 43372
Cross-posted to: comp.programming,comp.sys.atari.st.tech,comp.sys.m68k

Most compilers and/or runtime libraries have built in stack overflow checking unless you specifically disable it. Others require a special option to *enable* it. The bottom line here is to check your compiler docs to be sure.

(FYI dept: Sozobon/HSC checks for stack overflow on every DOS/BIOS/XBIOS call. The new release (1.40) will handle the check properly when you make a system call from supervisor mode; the current version can lead to spurious stack overflow errors in super mode.)

As to how to use the stack...well, there are as many answers as there are programmers. Most compilers/libraries give you a method to set the stacksize. If you want to use deep recursion or large stack-based buffers or other local data, you should specify an appropriate stack size using whatever method your tools provide.

3025. BoozGEM 2.1.3 and WX_Lib 1.0

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-04 22:30:17 UTC
From: MDORMAN1@ua1vm.ua.edu
Message-ID: <16839F629.MDORMAN1@ua1vm.ua.edu>
Source record: 43376
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

New postings to atari.archive:

BoozGEM 2.1.3 (file: boozgem3.zoo):
This is my port of Booz (the unZoo utility) to the Atari ST. It includes an integral GEM interface with menus and the whole lot. It also lets you extract a .ZOO file to a specific directory that you request (Happy, Roger?). You can also use the ``Install Application'' feature of the desktop, so that when you double click on a .ZOO file, it will automagically extract into the current directory. You can also do a ``Batch Extract'', which will take all of the .ZOO files in the directory you select, and extract them into subdirs inside the destination directory you choose. There's lots more (including the standard, CLI-based BOOZ.TTP), that's why I wrote a doc file for it.

The one problem: It doesn't support subdirectories inside of .ZOO files. The capability was unfortunately lacking in the original BOOZ sources. I'm slowly attempting to hack the appropriate routines out of the original zoo 2.1 source, but if anyone more conversant with the zoo 2.1 sources would like to volunteer to help, I would be most pleased.

Also newly uploaded is WX_Lib 1.0. This is a library of extended window management routines that allow you to open, close, move, size, clear and otherwise do efficient manipulation of GEM windows, as well as providing character-oriented output functions, including puts() and printf() clones that support automatic scrolling within the windows. An older, slower version was used to do the windowing support in BoozGEM. It includes support for HSC 1.33i/1.40 and GCC 2.1, object libraries for HSC & GCC, source code that compiles with GCC's "extra whiny" mode (-Wall) just fine, an example program, some docs, and the binary to the example program--one from HSC, one from GCC. Oh, it's only tested in GCC's 32-bit int mode--I have no idea what __mshort__ would do to it.

Download and enjoy, and please report any bugs or suggestions to me at mdorman1@ua1vm.ua.edu, or, preferably, mad@sss.cba.ua.edu.

Mike.

3026. Missing header files

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-05 01:26:02 UTC
From: azog@world.std.com
Message-ID: <BsHLBI.EJ2@world.std.com>
Source record: 43374

Hiyas. I am lacking the following header files, and am wondering if
they are available anyplace:

nlist.h
sys/socket.h
sys/un.h

I got my existing header files from MNTINC20. I also looked at the nlist.h
on my 3b1, and it looks like it could work. Its got defines for MC68k
(and others, which I removed).

Some of the stuff I am trying to compile wont go without these... Thanx

3027. The solution to the 128-byte command-line limitation

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-05 03:09:59 UTC
From: ae962@cleveland.Freenet.Edu
Message-ID: <1992Aug5.030959.15509@usenet.ins.cwru.edu>
Source record: 43375

After writing a command-line interpreter using LASER C, and having to deal with some of the problems Atari has created in limiting the command line of executed programs to 128 bytes, I have a few simple observations for those who still need to find out what is going on, and a few suggestions for those who intend to be part of the solution.

----- Definitions -----

There are several entities that will be discussed within this article that need to be described and named:

Pexec - Atari's operating system call that runs a program.
Shell - whatever runs a program by using Pexec.
Application - the program that is executed.
Parameters - command-line parameters passed to the program.
Variables - the environment variables the program may examine.
argv, envp - standard names the application uses to access the parameters and variables passed to it.

----- Simple general information -----

When an application is started by a shell, whether the shell be the GEM desktop, some special-purpose shell, or a command-line interpreter, the single instruction that ends up being performed is Pexec. Even Unix look-alike functions like "execve" that LASER C uses end up calling Pexec.

Unix C applications begin their main routine in this manner:

```
main (argc, argv, envp)
int argc;
char *argv[];
char *envp[];
```

and you therefore start the application by specifying argv and envp in the format you see here: each a NULL-terminated list of strings.

If Atari used this method of starting programs when it wrote the operating system, then there would be no problems whatsoever. However, for some unknown reason, they decided to create incompatibility with every known standard that exists in the civilized world and go ahead and do their own thing.

Here's what they decided: we will let the user have the envp variable list, but we will replace the argv parameter list with a 128-byte command line.

----- THIS WAS A GRIEVOUS MISTAKE! -----

For ordinary users, this wouldn't even be noticed. Double-clicking on an icon from the GEM desktop usually involves a command-line being generated that is blank or that has at most one word. This 128-byte command line would, for them, be large enough.

But for a very large number of programmers and software developers, this became an irritation. But why? Whoever uses more than 128 bytes when issuing a command?

Consider the following: you are running a shell and have about fifteen object modules in one directory to be linked together into a program. Ordinarily, you would use a compile and link utility like "cc" to generate the precise command-line for the "ld" link editor and would issue a command like:

cc -o test.prg *.o

The shell has the job of expanding the "*.o" into a list of all of the files in the current directory ending with ".o" just at that point in the command line. The shell would end up generating something like this:

cc -o test.prg first.o second.o third.o fourth.o fifth.o sixth.o seventh.o eighth.o ninth.o tenth.o eleventh.o twelvth.o thirteen.o fourteen.o fifteen.o

The resultant command line exceeds 128 bytes and therefore cannot be run directly as is using Pexec. Before the solution to this problem can be presented in this article, a few more background details must be explained.

----- Base page -----

When Pexec loads the program from disk into memory and passes it the command line, it does so using a memory structure called the "base page."

The base page is a 256-byte area of memory just below the first byte of executable code in the program. The first half consists of various data the program relies upon to correctly execute. The second half of the base page is the command line itself. Just prior to the first instruction being executed, Atari's program structure in memory consists of the base page, the text segment, the data segment, the bss segment, and then the stack, all on top of each other.

Pexec places into the base page the addresses of each segment and their lengths, as well as the bottom of the stack. Finally, Pexec changes the program counter to the first instruction of your program that is exactly 256 bytes above the base page.

Your program, since it is right on top of the base page, can refer to the data in the base page by immediately placing the program counter minus 256 into some address register as the very first instruction of the program.

Pexec does not allocate memory and then place your program in the allocated memory. It simply places it in memory unprotected and

unallocated, and passes the buck to the program.

----- Initialization code -----

The very first instructions of your program must therefore perform initialization. It must figure out from the base page how long the program itself is, then allocate that absolute block of memory. Then it must figure out from the stack size you specified where the top of the stack is, and set the stack pointer there.

For C programs, the initialization part of your program will then parse the command line within the base page and set up the argv string list. Furthermore, it sets envp to the appropriate address. Then, one or two instructions before the program quits, it calls "main" as a subroutine.

Remember that argv and envp are not part of the Atari operating system, and are provided only through the initialization code in your C program which tinkers with the command line and other data in the base page.

"But I never write initialization code!" True enough. Since the initialization process is standard and unchanging, LASER C and other C language development systems provide the code for you, WHICH IS SPECIFIED FIRST on the command line to the "ld" linker. In the case of LASER C, it is called "init.o".

The "ld" linker creates the program for you by looking at each file specified on the command line one at a time IN ORDER. Therefore, the initialization code, if it is to be executed first, is placed first on the command line to the linker. I use something like the following:

```
ld -o test.prg b:\megamax\init.o part1.o part2.o b:\megamax\libc.a
```

"But isn't 'main' executed first?" No. Whatever is placed first on the command line to the linker is executed first. Try linking with init.o later on in the command line and watch the resulting program crash. The initialization code calls main, so main must be in your code somewhere, but only in an artificial way so as to achieve C compatibility.

----- Shell special parameters -----

The shell may have parameters such as "hello there" or "*.*" or other things representing special parameters. "hello there" if placed directly on the command line by the shell will be interpreted by the program as "hello" and "there" -- two separate parameters rather than one. To obtain "hello there" as one parameter, the shell and the program have to COOPERATE and agree upon some standard. One standard would be to leave single apostrophes on either side of a string to be quoted as is like 'hello there'.

The parameter "*.*" would be expanded by the shell into a list of all files in the current directory. However, your program may want to obtain "*.*" as is and not have a list of files. This may be solved directly by

the shell if the shell and the user COOPERATE and agree upon some standard. One standard would be to use quotation marks on either side of the string like "*.*" and remove them before placing it on the command line.

Other special parameters exist such as ">outfile" that are not parameters at all but a special signal that the text output of the program that will be executed is to be redirected into the file "outfile" rather than printed on the screen.

It turns out that the initialization code of some programs will actually take 'hello there' and remove the quotes when it is placed into the parameter list, and handle the redirection of ">outfile" and "<infile" as well.

Be informed that Unix shells have been using and dealing with all of these things for a long time before the Atari ST even came on the scene. It would be worth your time to examine how "sh" or "csh" of Unix do their parsing and handling of the command line. It turns out that things like "> outfile" are handled by the shell, and not the program.

Special parameters have precise standards that have been successfully used for a long time in Unix, standards that don't need to be reinvented by Atari ST users, and standards that are perfectly acceptable. The command line and argv parameters are never anything other than character strings, that is, characters ending with binary zero. Methods of specifying binary zeros and other unusual or exceptional things should not even have to be addressed. Programs should not try to redefine what a string is.

Some off-the-wall programmer who wants binary data to be passed to his program as an ordinary condition should have his head examined. It can always be avoided, and characters strings like "100" have for a long time been converted to a binary integers, and taking only one line of code to do so.

Regardless of what kinds of special parameters you might have, it is a matter of cooperation between the SHELL and the APPLICATION and truly a separate problem from the 128-byte command-line limitation.

In an effort to solve the 128-byte limitation, we are beginning to see solutions combining the two problems of shell/application cooperation and the 128-byte limitation. THIS CONFUSION WILL RESULT in a contrived and unwieldy solution rather than a clear and simple solution.

It appears that already, people are willing to accept "clever solution" techniques involving magic numbers and bizarre manipulations of environment variables in order to quickly resolve things, as technicians want to do, rather than seeking out the simple and natural solution that makes sense and works better and that will pass the test of time for many years to come, as computer scientists want to do.

If 128 bytes is too short, lengthen it. Don't confuse the 128-byte limitation with the manner in which special parameters are to be

handled on a command line. Unix shells have methods by which you may deal with special parameters on the command line, and it certainly does not involve the environment variables. Much better to copy Unix shell methods and have a standard between Atari and Unix than to generate some off-the-wall solution no one in the civilized world has ever seen before or will see again.

----- Solution to the 128-byte limitation -----

Lengthen it.

That's it. Finished. All done. No more discussion. If 128 bytes is not long enough, make it longer. Don't you dare talk about special parameters. That is another issue entirely. It turns out that LASER C came up with a beautiful and elegant solution ALREADY to lengthen the command line. It is to use ONE environment variable with normal meaning and usage, a simple string in standard form:

MMARGV=the rest of the command line

All that the shell has to do, after doing all of the normal tasks such as shell expansion and replacement, is to examine the length of the command line. If it is too long, break it into two pieces, the first piece going the normal Atari command line, and the rest placed in MMARGV. Using the previous example of user input:

cc -o test.prg *.o

The shell expands it as usual into the following:

cc -o test.prg first.o second.o third.o fourth.o fifth.o sixth.o seventh.o eighth.o ninth.o tenth.o eleventh.o twelvth.o thirteen.o fourteen.o fifteen.o

and the shell, seeing that it is too long, breaks it into two pieces, where the command line gets as much as it can:

cc -o test.prg first.o second.o third.o fourth.o fifth.o sixth.o seventh.o eighth.o ninth.o tenth.o eleventh.o twelvth.o

and the MMARGV environment variable gets the rest:

MMARGV=thirteen.o fourteen.o fifteen.o

In this manner, all command lines less than 128 bytes would be used in Pexec normally, with MMARGV not defined, and all command lines greater than 128 bytes would be broken into the maximum size command line and one environment variable named MMARGV getting the remainder.

----- Final comments -----

This is the most simple, clear, and natural solution that can be conceived, that should cause no trouble at all to existing programs that read the command line. My command-line interpreter uses this and works very well with programs compiled with LASER C's initialization code.

If the name MMARGV bothers people, perhaps it should be changed to ARGV. However, this may cause a problem for programs that already use ARGV in their "clever solution" techniques. Furthermore, since LASER C, previously known as Megamax, came up with this idea, perhaps it should bear the name of the author, MegaMax, or MM, as contained in MMARGV.

In general, the best solution should be accepted even if that means a little extra work re-compiling older programs and upgrading the initialization code. The "clever solutions" will work, but are neither appropriate nor compatible with other systems, and will be guaranteed to create new problems in the future that will require even more "clever solutions" to fix the original clever solution -- I've been down that road, and it's full of potholes and detours.

----- LASER C documentation error -----

In their documentation, LASER C incorrectly states that the name of the extra environment variable is "ARGV". After disassembling their initialization code, I saw a string named "MMARGV" sitting there. This turns out to be the name you need.

> a few suggestions for those who intend to be part of the solution.

There already is a solution (i.e. an official, Atari sanctioned method of passing >128 bytes in the environment: the ARGV standard). I think you've misunderstood the discussion going on here: we're not arguing about how to pass long command lines (participants so far have taken the ARGV standard as a "given") but rather discussing how to overcome the one shortcoming of Atari's standard: it provides no way to pass null strings as parameters.

> If Atari used this method of starting programs when it wrote the
> operating system, then there would be no problems whatsoever. However,
> for some unknown reason, they decided to create incompatibility with
> every known standard that exists in the civilized world and go ahead
> and do their own thing.

(1) Atari didn't write that part of the operating system, Digital Research did. Credit where credit is due :-(.
(2) The most widely used operating system in the world, MS-DOS, uses the same method of passing arguments and environment variables.
I agree wholeheartedly with you that this misfeature of MS-DOS should *not* have been emulated, but to say that TOS is "incompatible with every known standard" is very misleading.

> Your program, since it is right on top of the base page, can refer to
> the data in the base page by immediately placing the program counter
> minus 256 into some address register as the very first instruction of
> the program.

Don't do this. I do *not* think it's guaranteed that the base page lies 256 bytes in front of the current program counter when the program starts. Rather, the address of the base page is pushed onto the stack before the program begins. Use the address on the stack.

(For example, if shared text is ever implemented, only the first copy of the shared text program will have a basepage at *-256; the second and subsequent copies will have basepages located at arbitrary positions in memory.)

> Pexec does not allocate memory and then place your program in the
> allocated memory. It simply places it in memory unprotected and
> unallocated, and passes the buck to the program.

THIS IS NOT TRUE. Pexec does the equivalent of a Malloc() call when
loading your program. It allocates the largest block possible. In most
cases, this is far more than the program needs, so the initialization
code should determine how much memory is needed and then perform
an Mshrink() call to reduce the size of the block allocated to the
program. Perhaps that is what you were thinking of.

> It appears that already, people are willing to accept "clever
> solution" techniques involving magic numbers and bizarre manipulations
> of environment variables in order to quickly resolve things, as
> technicians want to do, rather than seeking out the simple and natural
> solution that makes sense and works better and that will pass the test of
> time for many years to come, as computer scientists want to do.

I think Atari's solution is very simple: The last "variable" in the
environment is a string ARGV=something, followed by a list of arguments.
Each argument is a null terminated string. Thus, to do
echo a 'hello there' message
you would put:
ARGV=\0echo\0a\0hello there\0message\0\0
into the environment. (here '\0' represents binary 0, the NUL character)
You should also put a 127 byte as the "length" byte of the command line;
since no command line can actually be that many bytes long (the maximum
is 125, I think, for various arcane reasons) this serves as an indicator
to programs that the ARGV variable really is meant for them.

The shortcoming is that, since the environment is terminated by two \0's
in a row, it is impossible to pass an empty string as an argument
chracter.

Despite this shortcoming, Atari's method does have a number of advantages
over Laser C's:
(1) The program name is available as argv[0]. This is a rather large
advantage, since otherwise it can be very difficult for a program
to determine the name under which it was invoked.
(2) A standard way of indicating whether or not the ARGV variable is meant
for the program exists. (As an example of why this is important, suppose
a Laser C program (A.PRG) calls a non-Laser C utility (B.PRG). Since
B.PRG doesn't know what MMARGV means, it leaves the MMARGV= variable
in the environment. If B.PRG then calls a third program, MMARGV=
is still there in the environment, with an obvious potential for
confusion...
(3) Program startup code doesn't have to parse ARGV=, since this is done
by the shell. This means that there's no possibility of confusion over
how to parse arguments, or what quoting conventions should be used
(does that '"*"' mean 'expand all file names', or is it a literal
asterix?)
(4) Finally, and perhaps most importantly, it *is* a standard. Mark Williams
C uses it. Most ports of GNU utilities (including GNU C and GNU Make)

use it. The MiNT library, gcc library, tcsh, gulaam, bash, and ksh all use ARGV. And Atari has officially endorsed this standard, so it is possible that future releases of TOS will have it built into the desktop and/or other Atari utilities.

> Pattie Rayl (Atari Interface)

Thanks for the help, Pattie, however, with the current set-up I have, there should be no problems with v2.1 (The manual states there should be no problems using v2.1 with 1MB except limited doc. size.). As I said, no-one seems to know why the program runs perfectly for any document of reasonable size, prints out properly when printing is attempted for the first time in the session, then simply crashes when you attempt to print again. This problem seems to be simply bad memory management, however the menu bar being garbled is completely unexplainable, and can only be caused (I think) by a bug in the program itself.

I think I have solved the problem of changing fonts. It seems that one of the font disks had become corrupted, and the required data was no longer loading.

Do you, or anyone else, know of a printer driver specifically for the Epson LQ-100 printer? The printer manual states that a driver for the LQ-870 or LQ-570 should also be effective.

I have one more problem that you may be able to help with. How do you successfully print to floppy disk? This never seems to work for me...

Thanks in advance,
Big Stu.

3031. PC hard-drives and STs ....

Source record: 43380

Greetings,
I have access to a number of Seagate 40Mb hard drives which have
recently been culled from old PCs. The question I put to you techie types is
this :

Is it possible to use these drives with the ST? If so, how easy
is it (ie. does it require huge amounts of soldering and assorted
motherboard butchery) and if it can't be done, why not?

Has anyone managed to attach an ex-PC hard drive to their ST and get the ST
to talk to it? What about hard-disk controllers etc.?

Any information, technical or otherwise, would be greatly appreciated.

Thanks in advance.

Simon.

>but that should be no problem).
>[...]

What you are suggesting is a NEW method, that is completely incompatible with both ARGV and old style programs. IF we really don't care about defining a new incompatible standard, there's of course an absolutely straightforward way:

Change ARGV in only two aspects:

- Replace 'ARGV' by 'ARGV2' or whatever
- Add a trailing dummy char (perhaps a blank) to _every_ argument.

This would have at least the benefit that it's trivial to write startup codes that support both ARGV and ARGV2 (and equally trvial to extend spawn()).

All we would need is a method for shells to find out whether a program understands the new method. That *could* be done by defining a new standard extension for TTP type programs.

>This would have implications for the ARGV scheme, since this would expect
>127 as length. An alternative to changing ARGV would then be to include
>the next tail char, saying that if tail[0]==127 then we are using ARGV
>and if tail[1]==255 (or some other appropriate value then we are using
>ARG0 (just a sugestion for the name).

This will break all NON-argv programs.

Take care: pin 8 is not really ground:
In most system it is a 12V supply (but max 10mA) useful when plugging
in a SCART TV: the TV set detects this 12V and switches to 'video' mode !

Anyway, you've got to check, if you need it: some STs just have GND on
pin 8 instead of 12V.

No, I don't think this is the memory configuration problem:

A 3MB upgrade works by pretending it is 4MB: the hardware haven't got any
problems with it. The only trouble is that a 1M segment is accessible from
two different locations. This problem is solved by the TOS which checks
memory at start and after the first fault (after 3MB) notice that the
main memory is 3MB.

The problem is rather in the upgrade itself: bad connections or something
like that.

: David P. Forrai
: uucp: ...!{decvax,hplabs,ncar,purdue,rutgers}!gatech!prism!gt1448b
: Internet: gt1448b@prism.gatech.edu

I never heard about rectangular MMUs. The only custom chips I know
that are DIL are the Shifter and the DMA. It could be a confusion.

MMUs limited to 1M sound even stranger to me: some don't work with
2.5M but I believe they all work with 4M.

The pads you're talking about seem to be the ones that select the ROM
types (1M = 2 chips, 256K = 6 chips).

The blitter is a PLCC device available as every other custom chip
(MMU, DMA,...) for about 90 SFr (maybe 50$, maybe less). Like
every chip it should be socketed when enough place is available.
But in your case it seems Atari decided to lower its costs by
soldering directly on the board (SMD): you can try to do it but
prepare to the worst: soldering such chips is not great fun
as it was not conceived for this purpose (unless you have access
to a wave-soldering station or anything comparable). Anyway the
blitter is too expensive compared to the gain in speed: NVDI
is much more valuable.

Have fun with your 4M upgrade !

|
|After writing a command-line interpreter using LASER C, and having to
|deal with some of the problems Atari has created in limiting the
|command line of executed programs to 128 bytes, I have a few simple
|observations for those who still need to find out what is going on, and
|a few suggestions for those who intend to be part of the solution.
|

The problem is not one of absolute length, but the difference between

```
% echo " hello world"
hello world
```

and

```
echo hello world
hello world (notice all the formatting has gone)
```

The 128 (in fact 125) char space separated string *is* an abomination,
but there is an official Atari approved method of solving this (except for
the NULL arg problem, which is what everyone else is talking about)
Mail me and I'll send you a copy of what Alan Pratt said here some time ago.

```
|Unix C applications begin their main routine in this manner:
|
| main (argc, argv, envp)
| int argc;
| char *argv[];
| char *envp[];
|
...
|Here's what they decided: we will let the user have the envp variable
|list, but we will replace the argv parameter list with a 128-byte
|command line.
|
|----- THIS WAS A GRIEVOUS MISTAKE! -----
|
```

Yes, certainly. Bit too late to fiddle with now though...

```
|If Atari used this method of starting programs when it wrote the
|operating system, then there would be no problems whatsoever. However,
|for some unknown reason, they decided to create incompatibility with
|every known standard that exists in the civilized world and go ahead
|and do their own thing.
```

|

This, I believe was Digital Research's fault. It is inherited from CPM68k
and MSDOS (are you saying MSDOS is *not* a standard ? Perhaps just not
in a civilised world :-)

|Your program, since it is right on top of the base page, can refer to
|the data in the base page by immediately placing the program counter
|minus 256 into some address register as the very first instruction of
|the program.
|
Um, no. Spose your prgram has been loaded and run with some of the
more esoteric forms of Pexec. Your basepage *could* be anywhere.
PRGs TTPs and TOSs have the basepage passed on the stack. Look there.

|Pexec does not allocate memory and then place your program in the
|allocated memory. It simply places it in memory unprotected and
|unallocated, and passes the buck to the program.
|

This is completely backwards !! Pexec allocates *all* of memory to
your program (well the largest block). You then have to *deallocate*
the stuff you don't want with Mshrink.

|For C programs, the initialization part of your program will then parse
|the command line within the base page and set up the argv string list.
|Furthermore, it sets envp to the appropriate address. Then, one or two
|instructions before the program quits, it calls "main" as a
|subroutine.
|

Did you learn all this by disassembling the Laser C startup code ? I think
you may need some better documentation.

|"But isn't 'main' executed first?" No. Whatever is placed first on
|the command line to the linker is executed first. Try linking with
|init.o later on in the command line and watch the resulting program
|crash. The initialization code calls main, so main must be in your
|code somewhere, but only in an artificial way so as to achieve C
|compatibility.
|

This is true on *all* platforms that I'm aware of. I know a lot about
Unix, and I certainly don't believe that much crt.o (the usual Unix name
for the Laser init.o) code is very different.
What gets pushed onto the stack when a program is exec()ed and what gets
passed to main() could be very, very different.

|----- Shell special parameters -----
|
|The shell may have parameters such as "hello there" or "*.*" or other
|things representing special parameters. "hello there" if placed
|directly on the command line by the shell will be interpreted by the

|program as "hello" and "there" -- two separate parameters rather than
|one. To obtain "hello there" as one parameter, the shell and the
|program have to COOPERATE and agree upon some standard. One standard
|would be to leave single apostrophes on either side of a string to be
|quoted as is like 'hello there'.
|
|The parameter "*.*" would be expanded by the shell into a list of all files
|in the current directory. However, your program may want to obtain "*.*"
|as is and not have a list of files. This may be solved directly by
|the shell if the shell and the user COOPERATE and agree upon some
|standard. One standard would be to use quotation marks on either side
|of the string like "*.*" and remove them before placing it on the
|command line.
|

This is entirely the shell's job. If the shell sees * it can glob it.
if the shell sees * or '*' (or whatever quoting method the shell uses)
it should strip the quotes and pass the asterisk. Startup code should
never have to do file name globbing.

|Other special parameters exist such as ">outfile" that are not parameters
|at all but a special signal that the text output of the program
|that will be executed is to be redirected into the file "outfile" rather
|than printed on the screen.
|
|It turns out that the initialization code of some programs will actually
|take 'hello there' and remove the quotes when it is placed into the
|parameter list, and handle the redirection of ">outfile" and "<infile"
|as well.
|

Eeek. Which startup code is that ? The startuip code shouldn't be stripping
quotes and the shell should be doing input/output redirection (using
Fforce() on the ST)

|Be informed that Unix shells have been using and dealing with all
|of these things for a long time before the Atari ST even came on the
|scene. It would be worth your time to examine how "sh" or "csh" of
|Unix do their parsing and handling of the command line. It turns out
|that things like "> outfile" are handled by the shell, and not the program.
|
It may be worth you time to examine sh or csh (or tcsh or ksh.....) on
the ST. They work the *same* way.

|[...] Methods of specifying
|binary zeros and other unusual or exceptional things should not even have
|to be addressed. Programs should not try to redefine what a string is.
|
So how do you pass a binary zero (you *do* mean ascii \0 ?) in the *middle*
of a string ? The NULL is a terminator.

|Some off-the-wall programmer who wants binary data to be passed to his
|program as an ordinary condition should have his head examined. It can
|always be avoided, and characters strings like "100" have for a long
|time been converted to a binary integers, and taking only one line of
|code to do so.
|
MMdf mail files, and SCCS files use ^A (\001) as special markers. I might
easily want to grep for these or use tr to delete them. Passing special
characters on the command line is a real issue.

|In an effort to solve the 128-byte limitation, we are beginning to see
|solutions combining the two problems of shell/application cooperation
|and the 128-byte limitation. THIS CONFUSION WILL RESULT in a contrived
|and unwieldy solution rather than a clear and simple solution.
|
|It appears that already, people are willing to accept "clever
|solution" techniques involving magic numbers and bizarre manipulations
|of environment variables in order to quickly resolve things, as
|technicians want to do, rather than seeking out the simple and natural
|solution that makes sense and works better and that will pass the test of
|time for many years to come, as computer scientists want to do.
|

My copy of the Atari ARGV standard dates from August 1990. The people
currently talking about ARGV have not just pulled it out of thin air in
the past couple of weeks. It *is* a bit of a kludge, but anything else
would break too many other things.

|
|----- Solution to the 128-byte limitation -----
|
|Lengthen it.
|
|That's it. Finished. All done. No more discussion. If 128 bytes
|is not long enough, make it longer. Don't you dare talk about special
|parameters. That is another issue entirely.

This is not a solution. The arguments should *not* be one long string.
You've seen an argv[] array, it's lots of little strings, with null
terminators. How can you know from one string where to break it ? You
can't so everyone uses ARGV=

|... It turns out that LASER
|C came up with a beautiful and elegant solution ALREADY to lengthen
|the command line. It is to use ONE environment variable with normal
|meaning and usage, a simple string in standard form:
|
| MMARGV=the rest of the command line

Um really ? I'm not familiar with Laser, but I'd junk it if I were
you. the rest of the world uses ARGV now.

```
|This is the most simple, clear, and natural solution that can be conceived,
|that should cause no trouble at all to existing programs that read the
|command line. My command-line interpreter uses this and works very well
|with programs compiled with LASER C's initialization code.
|
```

But not with everyone elses... You don't use GNU make, Emacs, RCS, tcsh
or any of the host of wonderful UNIX ports and other utils ?

```
|----- LASER C documentation error -----
|
|In their documentation, LASER C incorrectly states that the name of the
|extra environment variable is "ARGV". After disassembling their
|initialization code, I saw a string named "MMARGV" sitting there. This
|turns out to be the name you need.
|
```

And you checked the start address right ? You'd look silly if it were

```
short foo = 19789; /* 'MM' in ascii */
char *arg = "ARGV";
```

```

I would prefer
ARGV=\0/bin/arrgh\0foo\0\\0\0bar\0baz\0\\0\0zip\0\0
that means passing empty strings "" by "\\0" two chars: backslash zero

Wrong. If you do that, the string "\001" is passed to the child.
There's no ASCII value 1 in that string.

My brother had the same problem and I put out a request on the network several months ago for advice on Pagestream.

The two main pieces of advice which appeared were

Buy more memory (he now has 2.5) and buy a hard disk!

The latter was a little too expensive. The only solution appears to be to save often!

Good luck
Mark.

>Wrong. If you do that, the string "\001" is passed to the child.
>There's no ASCII value 1 in that string.

Sorry. I goofed again and gave an incorrect example. I used the
wrong quotes since I'm now in the habit of using rc instead of ksh.
In ksh it would be

grep "\001" *

tr "\001" '^' <file >output

In rc, because quotes are really quotes, you would have to use printf
utility to perform the conversion of the octal escape into a single
character string.

grep `{printf '\001'} *

tr `{printf '\001'} '^' <file >output

Regardless of my poor examples. It may be said that a string parameter
could contain an ASCII value 1 as the first character of the string,

which still means that the \1 escape format would break.

It also allocates memory for the environment string beforehand, which
brings me to:

Say Eric since you are basically in charge of GEMDOS nowadays..,

Couldn't you use some of the reserved bytes in the basepage as a simple
pointer to a 'real' argument string. Basically the same way as
the environment is setup (by Atari GEMDOS since day one) by Pexec
could be used to malloc some bytes for the argstring and copy it threre.
Future startup files then need only look at a specified address in the
basepage. If that's non-0 it's a pointer to the 'only true and real'
argument string. If the pointer is 0, then we still could go with the
other braindamage.

Nat!
P.S. Passing in binary data thru arguments is IMO totally stupid. Use the
appropriate datatypes for the appropriate data. Use a FILE!

3045. Second&last time: Hacking Contest

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-05 19:30:24 UTC
From: wallmann@backus.pu.informatik.th-darmstadt.de
Message-ID: <1992Aug05.193024.20887@infoserver.th-darmstadt.de>
Source record: 43144

Judging from the gigantic turnout, you people are either
1 hacking away merrily and sending stuff in on the last day
2 think this is a joke
3 are too clueless to get more than 14 points (har)
4 think the prize is too lame
5 generally not interested in contests

So in case of number 2: this is not intended as a joke. There are
at least 60 points that can be scored.
In case of number 3: send in your 14 points Setcolor/Setpalette
code and win!
In case of number 4: well I think I can add something see far
below!

So this is the second and last announcement of a

HACKING-CONTEST

Change the screen color on a normal ST using only those XBIOS,
BIOS and GEMDOS calls that have been available since TOS 1.2 in
-as many different ways- as possible. Each entry is scored
according to this table:

Changes color voluntarily +7 pts ; these two are of course!
Changes color +4 pts ; mutually exclusive
Being resolution dependent -1 pts
Crashes after changing color
or terminating -2 pts
Crashes w/o changing color -3 pts
Used same idea with a different
system call 1 pts max. for this entry
Used small modification of the
same idea with the same system
call 0 pts max. for this entry
Uses any non-TOS calls anywhere 0 pts max. for this entry
Uses Supexec or Super anywhere 0 pts max. for this entry

Solutions depending on special hardware can not be accepted.

With changing colors voluntarily I mean, that you have full control
over the (16-bit) color value.
All points are added, the one with the most points wins!
You have to accept that the way points are given are solely my own
judgement.

Each entry should be a *seperate* little source of working
code in C and/or assembler. Please write as compiler/assembler
unspecific as possible. A comment here and there might help.

Remember: Just use XBIOS, GEMDOS and BIOS calls, that have been
available since TOS 1.2.

****
* The end of the contest is 23.59 of Sunday (9 Aug. 1992) *
* Mail your entries to: *
* wallmann@backus.pu.informatik.th-darmstadt.de *
* Use this in your "Subject:" line: *
* CONTEST: <yourname> ANONYMOUS: [n/y] ACK: [n/y] *
****

You may indicate whether you want an ACK that your entry has arrived,
and also you may choose to remain anonymous if you so desire. You can
of course use an assumed name as <yourname>, which will then be used
in the final result list. You may send in your entries trickle-like
one after the other. You may send your code uuencoded in .ARCed,
.ZOOed or .LHArced form.

The winner(s) will receive (for lack of sponsors) a purely symbolic
prize in form of a custom "SO WATT Carebears Demo"-ripper.
Of course the results and all the code examples will be posted to the
net.

Nat!

HINT: With <way> I don't mean just setting different colors or using
LSR.W instead of MOVE.W or using the same method accessing different
memory locations.

Bonus: Score in excess of 49 points and you will get access to
an exlusive ST sample replay library, with the following
features:

- links with PureC
- runs in the background at any selected speed
- mixes samples
- speeds/slows samples
- volumes samples
- plays in full quality
- takes 47% CPU when playing at 7.6Khz mixing four speeded
and volumed samples
- takes 49% CPU playing two regular samples at 12.5KHz

Not available anywhere else. Only thru this special offer! (har)

Organization: Nyx, Public Access Unix at U. of Denver Math/CS dept.
X-Disclaimer: Nyx is a public access Unix system run by the University
of Denver for the Denver community. The University has neither
control over nor responsibility for the opinions of users.

Jeez, I can't quite decide whether that was an attempt to flame Atari on
design decisions made 7-8 years ago, or just a bunch of rambling based on
misconceptions and misunderstandings of the issues. A few points I just
can't let slide, lest folks believe they might be accurate:

> Atari...decided to create incompatibility with every know standard
> that exists...and do their own thing.

If you don't even know the background that TOS evolved from, I'm not sure
how valid anything said beyond that point may be. Incompatible with every
known standard? I think not. Ever heard of MSDOS? The way TOS passes
env and arg data is compatible with it. You may not like MSDOS, but you
have to admit that it's running on enough millions of machines to make
it a standard unto itself.

> let the user have an envp variable, but pass the argv list...

GEMDOS doesn't pass an envp list or anything remotely like it. It passes
env data in a well-defined format (again, the MSDOS standard format), and
the init code has to build an envp[] list from it.

> Pexec does not allocate memory and then place your program in the
> allocated memory. It simply places it in memory unprotected and
> unallocated, and passes the buck to the program.

That's just compeletely wrong. In one special case, Pexec(3,...), the
parent program can retain ownership of the memory of the child process.\
It created enough problems that Atari added a new version of the "just go"
Pexec() that transfers ownership of the memory to the child (as it should
have been in the first place). Anyway, that's a real corner case, since
the normal usage of Pexec is mode 0, load-and-go. In that case, Pexec
allocates the env data area, fills it in, then it allocates the biggest
chunk available in the tpa, builds the basepage, loads the program into,
transfers ownership of the env data and tpa blocks to the child, and starts
the child process. The memory into which the child is loaded is not
"unprotected and unallocated". Even in the case of Pexec(3,...) the
memory is not unprotected and unallocated, because the parent program owns
the tpa. If anything else were the case, then the first time a child
tried to do a Malloc() it would be assigned memory from the "unprotected
and unallocated" block you've claimed it is loaded in, and it would
overwrite itself.

> solution to the 128-byte length problem: lengthen it.

Get crucial. I suppose you've rewritten TOS to fix the problem, and you're going to burn new ROMs and have them in the mail to all ST owners next week?

> MMARGV env var holds the overflow from the command line.

Hmmm, maybe this is why I hear some many folks complaining that their Laser C programs, and the Laser shell in general, just doesn't work right? Especially when folks try to run a non-Laser program from the shell that then fires up a Laser program as a child?

The scheme has two drawbacks: there's no validation to prevent passthrough of the MMARGV data through an unaware application to an aware application, and so the overflow args can end up being passed to the wrong program.

And, more to the point of this discussion: I see no allowances for passing null args. You get that \0\0 sequence into either the commandline image in the basepage or the env data, and that's the end of your args right there.

I did think of doing something like this in MiNT, but there are two possible
compatibility problems:

(1) I'm not sure which reserved bytes GEMDOS actually uses (I know that
it uses some). If we happen to choose some bytes that GEMDOS does use,
then programs starting up under old versions of GEMDOS might see
a non-zero "new argument field" even though there are no new arguments.
(2) All the Pexec parameters are used up. We could invent some new Pexec
modes, I suppose, but then this creates other backwards compatibility
problems.

I think the ARGV= environment method of passing parameters is pretty
good, *except* for the inability to pass empty parameters. If we can
find a solution to that, then I don't think there's a need for a new
mechanism in TOS itself.

If they use your code in MTOS, you should have enough weight of getting
a final word out of the guy in Atari who's in charge of the GEMDOS code, which
of the over 40 (at least) unused bytes are really unused.

>(2) All the Pexec parameters are used up. We could invent some new Pexec
> modes, I suppose, but then this creates other backwards compatibility
> problems.
Mmmh, I don't get this. Why would we need another Pexec parameter? We could
just use the old cmdline thing. Since as far as I know the format of the
command lines is like this:

length.b, argstring[something less than128]
^

Then setting length to 128 we know that the actual argument string is
longer. So then to get the length of the argstring you'd do strlen
over it. Or if this empty parameter stuff is really that important, one
could do.

length.b, real_length.l argstring

so that you can pass in everything you want.
Needless to say, this would be only upwards compatible. (but old code
won't crash).

>I think the ARGV= environment method of passing parameters is pretty
>good, *except* for the inability to pass empty parameters. If we can
>find a solution to that, then I don't think there's a need for a new

Sure as a user, I don't care which way it goes. As a programmer this
ARGV method isn't really the embodiement of slickness I like to see
in an OS.

Nat!
BTW. Congratulations to MiNT, great great stuff.

Sorry yet one more.

A point that is apparently unclear:

Changing the background color is meant. ANYthing that
changes it is acceptable! If it runs only on monochrome, but
the idea also translates to color. Zero problem!

What would for instance work is "painting the monitor green.
photographing the result, digitizing it, encapsulating it
in a small program and somehow displaying it on the screen
(using ye olde TOS1.2 calls)".
Whoops gave away a four pointer.

If you want an idea you may write in and ask for one of the
following: basic hackish rule-abusing

Of course you can't make any points on those then anymore,
nor on related entries. (your email will be stored in our
electronic store and retrieval system 'mbox' (har))

Nat!

[ian explains the intracacies of Pexec environments...]

ok. i understand. thanx. i still wish there was a way to pass a ptr and
for the child to be able to use it with out getting a copy, but i realize
this could be dangerous (since the child could modify the parent's env).

In article <1992Aug4.153845.13383@mks.com> ant@mks.com (Anthony Howe) writes:
>It might be the case that I wish to grep for all such lines in a file.
>
> grep '\001' *

does the shell actually expand the 4 char sequence "\001" to be a single
char "^A"? if so, u are correct.

>Or translate them from ^A to caret
>
> tr '\001' '^' <file >output

if you escape the escape
(ie \\001), then tr will get a string "\001" as its first arg and will do
the escape parsing. if the shell, however, parses the line and converts
the \001 to ^A, you are correct (and validate my previous argument).

i will have to try this since i don't know the answer off the top of my
head...

this is the best reason so far for not using the \1 thing without ian's
modifications to the idea...

also note that things like "echo ^G" are not uncommon (^G being a single
char). or maybe "sed -e 's^G/foo^G/bar^G' file". the latter has a workaround.
the former does not.

Even with my modifications the \1 escape fails the "will it break
existing aps?" question now. I'm brainstorming...

>a *change* to grep source code that is required, just the crt0.o it was
>linked with.

[i think u mean it is NOT a change to the grep source code...]

what if i have an old (pre-ARGV2) shell and a new (post-ARGV2) tool?
your argument assumes a new shell and old tools. recall what happened
with LHarc when new archives appeard (analogous to new format tools) and
everyone had old lharc programs (analogous to old format shells). total
chaos, that's what...

if i have an echo program compiled with the new ARGV with the space
stuff, then if i do echo " " from an old shell, echo will find the space,
delete it, and not print anything (since it would be a null arg). which means
the shell and echo are out of sync WRT ARGV. this is stupid and a horrible
compatibility problem. IMHO it IS a big deal. saying "oh well,....until
i get a recompiled version" with several hundred programs and perhaps scores
of existing scripts from many different sources would be a nightmare. the
space thing would probably require total recompilation of every shell and
tool. it is NOT a simple matter!!! personally, if i want " " passed, i
expect " ", not " " no matter what version of ARGV i have on either side of
the Pexec.

at least the \1 scheme only breaks programs (not shells) which may want
bona fide binary data in args. there are fewer of these. while i think it
is important enough to not break this, it is the lesser evil between these
two schemes. as far as i can see, this is the only fault of the \1 scheme.
it has no other impact on either side of the transition. ian pointed this
out quite adequately. some of the progs that \1 breaks have workarounds
(like the tr example mentioned since it will parse args given as escapes).
"some", however, is not "all". hence the dilema. if grep is the only
program that really needs a null arg, and if there is a workaround, it
is hardly worth the effort to propose a totally new scheme to handle it.
just pass the default regex as a real arg. problem solved (portably).

i go back to my original question: how many things are broken if we leave
things alone (and what is the impact of their "brokenness") vs how many

things will break if we change to a new scheme? do we really have a problem to solve here? i don't know the answer, but my guess is "we don't really have a problem (yet)". this is based on personal experience with the number of times i actually have to pass null args to a program (very few times). personally, i use args with just spaces more often (even these are fairly rare). i think we should use POSIX.2 as our guide and see how close we can get to it without severe impact. severity is a subjective thing. of peripheral interest is the additional internet traffic generated by everyone scrambling to get a full set of recompiled tools after whatever proposal is adopted (if any). until we can answer this question, there is no need for any new proposal. i don't have POSIX.2 so i can't answer this.

whatever standard is adopted should assume that there will be a mixture of programs "before" and "after" adoption that must work together as if nothing happened. i don't think this is 100% possible with any of the suggested schemes. if there is no "100%" proposal, then we have to assess what impact a "99.5%" proposal will have on the 0.5% of broken stuff. i would estimate tha \1 scheme to be a "95%" proposal as it now stands. i would guestimate the space scheme to be a "50%" proposal...

In article <A45005@MS.maus.de> Julian_Reschke@ms.maus.de (Julian Reschke) writes:
>Anyway: I still don't like the idea of warping the mouse cursor, BUT
>I am still sure that it can be done with appl_tplay. Whoever wanted
>to know that: please tell us what you did try and in what way it didn't
>work.

the reason i suggested vex_motv are threefold: 1) "most" people don't have multitasking GEM so this won't be too much of a problem, 2) it is a fully documented VDI routine and hence _should_ be portable, 3) the last time i tried appl_tplay it (also) did not work. this was probably at either TOS 1.0 or 1.2. if you explain how to use this with TOS <= 1.4, i'd also appreciate it.

i suggest that a full list of "do's and don't's" be listed for multitasking consideration. then i suggest atari generate backward compatible TOS upgrades for singletasking users. no offence, but i am getting tired of hearing that everything that has fully documented and sanctioned to this point will break under some new scenario. if appl_tplay is broken in 1.0, you are saying there is no "portable" solution to this "problem". BTW i agree that mouse warping is probably not a good idea anyway except in very select cases.

note that the scheme that i used should not break in multitasking situation since it is only operational during a mouse button down state (dragging) which should only be handled by a single application. in my case, i limited the x,y position of the mouse to the work area of the window until the button was released. i can't see how this can be effected by multitasking.

in the case of dialogs, are you really saying that a user might be able to move to another application before handling the dialog? is there a way to lock out a user from doing this (and therefore making a vex_motv legitimate if it is only temporary during the dialog itself)?

what i was proposing was something like:

```
event=evnt_multi(...);

wind_update(BEG_UPDATE);
...
if (whatever)
{
vex_motv(...set_it...);
poke in "new" position in d0.w,d1.w in new handler
vex_motv(...reset_it...);
do_dialog(..);
}
```

```
...
wind_update(END_UPDATE);
```

do u really think that there is a multitasking issue here? does not the wind_update(BEGIN) disable GEM from doing anything anyway? it might need wind_update(BEG_MCTRL) for mouse, too. i did this years ago and forget. also, i thought there is a one to one correspondence between handles and applications (is vex_motv global, and if so, why does it have a handle arg? oh, i think it is the handle for the screen, so this might explain it. i should bone up on GEM some more...). also the reset vex_motv might have to be after the dialog.

my docs say about BEG_UPDATE: "Notify the AES that the application is about to update a window. During this update, the AES does not allow the user to interact with the windows." i assume this means ALL applications running. and BEG_MCTRL sez: "Notify the AES that the application is taking control of all mouse functions. while the application has control of the mouse functions, the Screen Manager does not respond to mouse input, and menus and window control are not active unless handled by the application." it seems to be pretty clear that these tell the AES and screen manager to leave us alone until we tell you it's ok. what impact does multitasking have on these basic functions?

thanx, julian... :-)

3056. Null arguments with ARGV

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-06 00:41:12 UTC
From: 7103_2622@uwovax.uwo.ca
Message-ID: <1992Aug5.204112.1@uwovax.uwo.ca>
Source record: 43156

It seems to me that we've narrowed the possible solutions to passing
null arguments to ARGV down to 2 basic ideas:

(1) Using an escape of some sort. Possibilities for this are:
1a) Using a whitespace character (e.g. space) as an escape, so
a null argument is passed as " ", a single space as " ",
and so on. This has the disadvantage that it breaks
existing programs that may want to have spaces passed as
arguments. Since there are a significant number of such
programs, it seems to me that this is a suboptimal solution.
1b) Using a binary character as an escape; for example, \001 or
0xff or 0x80. This will break programs that want that particular
binary character passed to them. For this reason, I would
suggest that only a non-ASCII character (i.e. greater than 127)
be used; this should minimize possible conflicts.
1c) Using a long, multicharacter escape sequence to indicate a null
argument; for example, perhaps "\001NULL ARG\001". If such a
sequence is detected as the first n bytes of an argument, it is
stripped from the argument. This has the advantage of making
accidental duplication of the escape sequence by older programs
very unlikely, at the cost of some extra complexity in the
startup code.

(2) Using the space after the ARGV= string itself to mark the positions
of null arguments. This method will only be feasible if it can be
done in a way that won't break existing programs. This is true of
programs compiled with the standard and MiNT gcc libraries (which
ignore the value of ARGV=). Can anyone supply some definite answers
about whether or not this will break MWC compiled programs?

The idea here would be to set ARGV equal to a special value which
indicates which positions are occupied by empty parameters: for
example:
2a) ARGV=NULL:2,3,12 indicating that argv[2], argv[3], and
argv[12] are empty
2b) ARGV=NULL:1100111111110 using a bitmap to indicate which
argv[] elements are full (1) or empty (0); in practice
it would be better to do this in base 16 or even base 128 to
save environment space.
In both cases, if there are no null arguments then the stuff
after ARGV= can be omitted, so that we end up with an implementation
which is exactly the same as the current standard.

My preference, I think, is for option 2; 2b should be easier for
startup code to parse (i.e. it could be done without dragging in library

functions like atoi()) but 2a takes less space. IF some variant of
option 2 can be implemented without breaking existing MWC compiled
programs, I would say let's go with it. The reason I prefer this to
escape codes is that it is entirely upward compatible; programs
that don't understand ARGV=NULL will see exactly what they would
have seen in the environment with the existing standard.

> make SHELL=d:/mint/bin/sh.ttp

The easiest, and IMO best, solution is to have

MAKEFILES=d:/etc/default.mak

and, in D:/etc/default.mak, put

SHELL=d:/mint/bin/sh.ttp

Other things can be put into d:/etc/default.mak, like rules for .ttp, .tos,
and .prg files, but that makes your makefiles a bit less portable.

3058. Re: The solution to the 128-byte command-line limitation

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-06 01:17:33 UTC
From: rosenkra@convex.com
Message-ID: <1992Aug06.011733.3677@convex.com>
Source record: 43157

how does laser C handle this:

grep "" file

argv[1] is a null string. if you want, you could also tell us how laser
C handles:

```
cmd xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx\
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx\
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx\
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx\
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx\
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
and
cmd xxxxxxxxxxxxxxxx xxxxxxxxxxxxxxxxxxx xxxxxxxxxxxxxxxxx\
xxxxxxxxxxxxxxxxxxx xxxxxxxxxxxxxxxxxxxxx xxxxxxxxxxxxxxx\
xxxxxxxxxxxxxxxxxxx xxxxxxxxxxxxxxxxxxxxx xxxxxxxxxxxxxxx\
xxxxxxxxxxxxxxxxxxx xxxxxxxxxxxxxxxxxxxxx xxxxxxxxxxxxxxx\
xxxxxxxxxxxxxxxx "" xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
^^ note the empty arg...
```

these are NOT pathalogical cases. the first (grep) is a real world situation.
the second can be considered the norm for doing things like RCS ci -t-"string"
where string can be really long. the last might be pathalogical, but i'd
like to see how it is done. :-)

Are they MFM drives? RLL drives? At the very least you will need an ACSI to SCSI convertor and if necessary an MFM or RLL (dependant on drive type) to SCSI controller. No modifications to the ST should be required as the DMA/ACSI port is already present in the case. Other than a source of power and hopefully an enclosure and fan, nothing else should be necessary as the software to format the disk and make it bootable should come with the host adapter.

If that is done, make sure to pick a character which has no meaning in
any language at all, also counting possible extensions like using
ASCII > 128 for Cyrillic, for example... in other words, no.

>I am still sure that it can be done with appl_tplay. Whoever wanted
>to know that: please tell us what you did try and in what way it didn't
>work.

I created a 6 byte buffer and stored in it a mouse event according to
the documentation that I have. The first 2 byte word contained a
2, which is supposed to denote a mouse event, the second 2 byte word
contained the x coordinate of the mouse, and the last word contained the
y coordinate of the mouse. I then called

appl_tplay(6_byte_buffer, 1, 1<various_numbers<10000);

The middle 1 is supposed to be the number of events to play, and
the last number is suppose to be the speed of replay. I tried several
numbers there.

Anyway, when I make this call, NOTHING happens. I can't make it do
anything. I received several messages telling me that the format
for the record buffer changed to 8 bytes in later versions of TOS,
but I have TOS 1.0. I tried various 8 byte buffers (it isn't clear
what goes where when you have 8 bytes) but all I got then were bombs.

Given that this is a major pain, and apparently wouldn't be portable,
I decided that it wasn't worth the effort. I was just trying to learn
some GEM.

I don't have any documentation on vex_motv, and I couldn't make any
sense out of the prototype in the vdi bindings. Exactly what does
this function do and why would it screw up? Just curious.

An implementation like this will not break existing programs, if you
don't try to deliver empty arguments to them (because ARGV= can be of
any value then). As Ian has pointed out, this problem is non-existent
because it was never possible to deliver empty arguments to any program
at all.

I absolutely agree with you.

I'd like to add the following proposal:

Empty arguments are not simply left out in the argument list but replaced
with a space. This gives unaware programs a better chance to understand
an argument list that contains null args (because the other arguments are
in the right place at least). Example:

"ARGV=NULL:2,4\0arg1\0 \0arg3\0 \0arg5\arg6\0\0"

ACH> octal escape sequences in strings.

Whatever escape character that one selects to denote a null argument,
one will have to be able to escape that character being entered in the
case that some program might need it (such as grep or tr, etc).

bye,

3065. Re: Null arguments with ARGV

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-06 12:55:39 UTC
From: ant@mks.com
Message-ID: <1992Aug6.125539.1887@mks.com>
Source record: 43164

I almost forgot that MKS has a similar convention for DOS which is
documented in their toolkit manual:

"MKS-compatible programs are able to receive their command
line arguments from the environment. These arguments must be
at the beginning of the environment and each such argument
begins with the tilde (~) character. The first argument that
does not begin with a ~ is the first character of the _real_
environment that should be scanned by getenv() in the C
library. This implies that in addition to requiring special
hooks in the runtime startup, this calling sequence requires a
specially modified getenv() to function properly. If the
following command were typed to the shell

grep *.c '' 'Hi there'

an environement like the following might be passed to grep:

~grep\0
~file1.c\0
~file2.c\0
~fred.c\0
~\0
~Hi there\0
PATH=\bin;\usr\bin;\0
SHELL=\usr\local\rc\0
\0

The command arguments may be read by scanning the enironment
segment in the obvious manner.

It is also important to clarify the situation where an
MKS-compatible shell calls a non-MKS command that in turn
calls another MKS command. In this situation, the MKS command
should use the standard 128 byte command line generated by the
non-MKS command rather than the expanded arguments from the
environment generated by the MKS- compatible shell. To allow
this, the 128 byte command line is written by the shell with
newline (\n) character after the standard carriage return
(\r). Neither of these characters is included in the command
tail count. "

This convention could be modified so that it would not be necessary to
have a special getenv(). All that would be required would be to do this
would be place a special character to act as a "End-of-Args" marker to
delimit the arguments from the _real_ environment. The C startup would

then modify its base->p_env to point to the real environment.

A similar better idea:

We could do something using the existing ARGV= convention. We could
still create an ARGV= that prefixed every argument with a tilde
(or space if people are so found of it) __AND__ place in the command line
count byte a different invalid length like 126 or 128 (remember the
command line is limited to 125 and the current ARGV expects 127 for
validation). The advantage of this means that newer C startups can
parse both ARGV= conventions and MWC can still use the ARGV= value.
The new C startup would determine which convention is in use, if at all,
by the command line length byte, and if the new convention is in use
strip the first character.

You might get more entries if the task was something moderately useful -
say fastest 32x32 non-blitter sprite code or least cpu intensive sample
replay code for a given frequency.

I just can't find the enthusiasm to write useless code when there is so much
useful code to be written. Sorry.

Steven

&> Some other guy wrote the classic "Get a life, dude"

Ok getting a little flamage for this idea. I will just try to explain that
I thought for people who know their ST it would be fun to explore some
ways you can abuse your usual TOS calls (or to abuse the rules).

Since every little -way- uses just about 10 lines of truly non-intricate
C-code, I thought even for those hardworking people (i myself at the
moment code about 12 hours daily 7 hours a week) it would be a fun idea
and not very time-consuming.
If I had used the above suggestions people would have accused me of
scamming them out of their codes.

It's like communism, the idea was good, but we couldn't find the people
for it (har). But that's ok.

I have NVDI installed on my system, and I haven't had that problem. Perhaps it's some other program in your system that's conflicting? You could try various combinations of BIOSBUF={YES,NO} and try with and without CON=u:\dev\fasttext in your mint.cnf.

I've got a 4- to 5-month-old TT with a Quantum LPS105S drive of the same age. The Quantum seems to act as if the WS (wait/spin option) jumper was installed, but it's not. Once the drive is accessed after a while of not doing anything, the activity light will come on for a few seconds and sound like it's doing its periodic seek; then it will do whatever accessing it was told to do. Any ideas as to what I can do other than getting it checked out/replaced?

The other German company, Steinberg, has cute little(?) thing called SMP II. It's a 19" rackunit 1 high. It gives you 2 in's and 4 out's plus some merge capabilites. This means 4*16 channels. It's also computer independent.

I too have heard the bit about about some MMU's not being able to deal with
more than 1M, even though the source was same, namely ST Format, but an older
number.

They listed a serial number that is on top of the faulty chip. I can dig it up,
if anyone is interested.

Hi.

Having seen the problems some of you had with a version of less as distributed on a,a, and after exchanging mail will Bill Rosenkranz, I have decided to post my own port of less to a.a.

I use this version every day on MiNT 0.94. It was compiled with gcc 2.1 and MiNT libs PL 19. The distribution includes full sources, plus an executable. To my knowledge, this less is fully functional: regexps, signals, shell escapes, line numbering, you name it.

To install, run the (Bourne) shell script linstall, then type make. The linstall script will create a makefile. Also read the file readme.st for information about changes.

Have fun.

The MWC startup code doesn't use the length byte for validation. Thus,
this convention will break existing MWC-compiled programs.
